Acknowledgements

Thank you to the participants of this study who generously volunteered their time and shared their enthusiasm for music, singing and life itself. Thank you also to the choral group organisers, musicians and associated organisations; this project wouldn’t have been possible without you.

Many thanks to Sarah Strohmaier and Emma Harding for your assistance in data collection, Rachel Hughes for completing initial analysis of the heart rate data and Dr Sabina Hulbert and Dr Daisy Fancourt for your invaluable help throughout data analysis.

Thank you to my supervisors Professor Paul Camic and Professor Sebastian Crutch for your unwavering support and encouragement at all stages of the project.

I would like to thank my family and friends for your love, laughs, patience and guidance over the last few years, I can't wait to spend more time with you! Particular thanks to Jess for being a brilliant housemate and amazing friend, bringing all the joy and right kinds of tears into my life and to Claire for your optimism and endless fun times. Special thanks to my dad, Bruce, for your unfailing belief in me and always being there with kind supportive words.

Finally, thank you to Gin and Gramps, (the OG Dr Bourne) for always inspiring me in every area of my life.
Summary of the Portfolio

Section A

This section contains a systematised literature review on the influence of community dyadic arts-based interventions on people with a dementia and their caregivers. Twelve peer-reviewed studies were included, five focusing on performing arts interventions and seven on visual arts. Findings suggest that arts interventions may have positive effects on psychological outcomes for both people with dementia and their informal caregivers, particularly based on qualitative data. The findings provide a rationale for further research addressing the methodological limitations of the current evidence base including the use of control groups and consistent quantitative outcome measures. Recommendations for clinical practice are also discussed.

Section B

This mixed methods, exploratory study investigated the influence of a dyadic choral singing group on people with a dementia and their caregivers. Physiological measures of stress (salivary cortisol and heart rate) were combined with subjective measures of wellbeing and stress and interviews. Quantitative data analysis showed positive effects of group singing on subjective stress and wellbeing. The majority of salivary cortisol results showed a decreasing trend and heart rate variability significantly increased for people with dementia. The thematic analysis revealed positive influences including effects on mood and cognition, aspects of the intervention associated with these effects were also described. The findings suggest that additional research is warranted to further investigate interactions between physiological and psychological variables related to choral singing in people with a dementia. Clinical and research implications are discussed.

Section A: Literature Review

Arts-based interventions for people with a dementia and their caregivers: A systematised literature review

Word count: 7199 (505)

Philippa Bourne BSc (Hons)

For submission to International Journal of Psychogeriatrics
Abstract

Dementia is a neurodegenerative condition that can lead to profound psychological challenges for people with dementia and their informal caregivers. Previous research has found positive effects of arts-based interventions for people with dementia and caregivers that have been dyadic in nature. A systematised literature review was conducted to investigate psychological outcomes of dyadic arts interventions delivered to both people with dementia and their caregivers. PsychINFO, Medline, Web of Science and ASSIA databases were searched as well as Google Scholar and reference lists of relevant studies. Twelve peer-reviewed journal articles met the criteria for inclusion in this review, five focusing on performing arts and seven on visual arts. The findings suggested that arts interventions may have positive effects on psychological outcomes for both people with dementia and their informal caregivers particularly based on qualitative findings. Improved wellbeing, quality of life and mood were reported in some studies. However, methodological limitations of the literature including small sample sizes, a lack of control groups and the lack of consistent quantitative outcome measures, make firm conclusions difficult to draw. Recommendations for clinical practice and further research were proposed.

Keywords: the arts, dementia, caregivers, dyad, psychological impact
**Introduction**

The term dementia refers to a set of neurodegenerative conditions that impact cognitive, behavioural and emotional functioning. It is most commonly diagnosed in older adults and there are estimated to be 850,000 people living in the UK with dementia (Prince et al., 2014). As a result of increased dementia awareness and diagnosis and older people living longer due to advances in healthcare, the number of people diagnosed with dementia is increasing (Lewis, Karlsberg Schaffer, Sussex, O’Neill, & Cockroft, 2014). As the dementias are progressive conditions, more areas of the brain are affected over time and more symptoms develop. Cognitive symptoms of dementia can include difficulties with memory, expressive language or comprehension, visuospatial skills, attention and orientation (Alzheimer’s Society, 2017). Other symptoms can include changes to behaviour (e.g. socially inappropriate behaviour) and psychological difficulties (e.g. depression). The most commonly diagnosed form of dementia is Alzheimer’s disease and other forms of dementia include vascular dementia (VD), frontotemporal dementia (FTD) and dementia with Lewy bodies (DLB).

**The impact of dementia on psychological functioning**

In addition to the cognitive and behavioural symptoms experienced by people with dementia, it can also have an impact on psychological and social functioning. People can develop difficulties with emotional regulation and a reduced capacity to deal with stress (Cheston, 1998). Following a diagnosis of dementia, a range of responses can be experienced including denial of difficulties/diagnosis, grief due to anticipatory loss and developing positive coping strategies (Aminzadeh, Byszewski, Molnar, & Eisner, 2007). Emotional difficulties including anxiety and depression can develop due to feelings of hopelessness, fear, anger and insecurity which can further impact on quality of life (QOL) (Bender & Cheston, 1997; Rusted, Sheppard, & Waller, 2006; Woods, 2001). Over time, psychological
difficulties and loss of independence can also lead to social withdrawal which can have a further impact on mood. Kitwood (1997) highlighted that people can also experience positive emotions including humour, pleasure and affection when their needs are being met.

**The impact of dementia on family caregivers**

Research has also investigated the impact of dementia on family caregivers. Pinquart and Sörensen (2003) highlighted that caregiving can maintain closeness and provide satisfaction for some caregivers, and Carbonneau, Caron and Desrosiers (2010) found that the role can be associated with increased wellbeing. However, the demands of caregiving and feelings of loss over the course of dementia can have a negative impact on caregiver wellbeing and be associated with increased stress and depression (Baikie, 2002; Balfour, 2014; Pinquart & Sörensen, 2003). Some interventions have been found to have positive effects on depression, burden and wellbeing of caregivers including counselling, social skills and behaviour management training and support groups (Pusey & Richards, 2001), although findings are mixed (Selwood, Johnston, Katona, Lyketsos, & Livingston, 2007).

**The impact of dementia on relationships**

Dementia can also have an impact on the relationship between the person and their informal caregiver(s), whether this is a spousal or other relationship (NICE, 2006). As the dementia progresses, there can be a change of roles, loss of closeness and intimacy and a reduction in shared activities (Baikie, 2002; Balfour, 2014). The concept of ‘couplehood’ in dementia literature refers to the relationship between a person with dementia and spousal caregiver (Hellström, Nolan, & Lundh, 2007). Hellström et al. (2007) found that couples positively focus on ‘sustaining couplehood’ and both attempt to maintain involvement in the relationship, although this can become increasingly difficult for people in the later stages of dementia. Merrick, Camic and O’Shaughnessy (2016) interviewed couples on the effects of
dementia from a relational perspective. One theme that emerged was of “altered structures”, focusing on how the structure and organisation of the relationship changes when one person has a diagnosis. This theme included changes in the level of reciprocity in the relationship, with fewer reciprocal conversations and less shared understanding. They also found that couples focused on maintaining normalcy and, in some cases, found a strengthening of the relationship. One aspect of sustaining couplehood involves shared activities and “doing things together” (Hellström, Nolan, & Lundh, 2005, p. 16). It is possible therefore that dyadic activities could support this concept of ‘couplehood’ and normalcy and help people to maintain these relationships. Discovering new ways to spend enjoyable time together (e.g. through shared activities), can also increase wellbeing and happiness for people with dementia and their caregivers (Carbonneau et al., 2010; Voelkl, 1998).

The arts

NICE guidelines (2006) for people with dementia recommend that they should be supported in engaging in activities they enjoy and one of the recommended treatments for non-cognitive symptoms of dementia (e.g. anxiety and apathy) is the use of music as a therapeutic tool. There are many different forms of arts interventions for people with dementia and their caregivers including visual, performing and literary arts. One type of performing arts intervention is music-based interventions and the majority utilize either music therapy, singing, music-listening or a combination of these. There has been a plethora of research into the influence of music-based interventions and therefore also numerous literature reviews. A recent Cochrane review concluded that they may have an impact on depressive symptoms for people with dementia (van der Steen et al., 2017). Only randomised control trials were included in this review and although most evidence was of low to medium quality, there was no conclusive evidence that music interventions had an impact on wellbeing, QOL, anxiety or agitation. Other papers reviewing the literature have concluded
that there is evidence that music interventions have a positive impact on mood and
behavioural disturbances (McDermott, Crellin, Ridder, & Orrell, 2013) and behavioural and
psychological symptoms of dementia (BPSD) (Raglio et al., 2012). However, the lack of
methodologically robust studies makes conclusions difficult to draw (Blackburn & Bradshaw,
2014; Vink, Bruinsma, & Scholten, 2004).

There are fewer reports involving visual arts interventions. Rentz (2002) and Kinney
and Rentz (2005) evaluated a visual arts programme called Memories in the Making© with
people with dementia attending day programmes or living in residential settings and found
increased pleasure, self-esteem and wellbeing following participation. Beard (2012)
conducted a review of the wider arts literature including visual arts and found positive effects
of these interventions on self-esteem and wellbeing, concluding that visual arts interventions
can play a meaningful role in the lives of people with dementia. However, she concluded that
further research is needed investigating effects from the viewpoint of the person with
dementia and those living in the community (Beard, 2012). Windle et al. (2017) recently
found that an art-viewing and art-making program increased wellbeing and QOL for
participants.

Literary arts interventions have included storytelling and reading. Reading groups
have been associated with reductions in the severity of BPSDs (as rated by professional
caregivers) and themes from interviews included enjoyment and links to renewed identity
(Billington, Carroll, Davis, Healey, & Kinderman, 2013). Phillips, Reid-Arndt and Pak
(2010) evaluated the impact of a TimeSlips storytelling intervention with people with
dementia and found improved communication skills and increased positive affect and
expressions of pleasure compared to a control group.
McDermott, Orrell, & Ridder (2014) developed the psychosocial model of music in dementia, highlighting that it is the interaction between “who you are”, the “here and now” and “connectedness” with others that contributes to the positive effects of music on people with dementia. Although this model was developed with people living in residential settings, the social benefits of connecting with others in the community, experiencing joy in the present moment and connecting with the person’s own identity are all likely to be important for those living in the community with dementia. As the other areas of arts-based interventions (visual and literary arts) are still in the early stages of research, there have yet to be developed specific theories for the possible effects of these activities. However, an art-viewing grounded theory study highlighted the importance of psychosocial programmes reducing “excess disability”, by focusing on people’s strengths and not underestimating their abilities (Macpherson, Bird, Anderson, Davis, & Blair, 2009). They also concluded that this provides support for the importance of supporting people with dementia to access “normal” activities such as arts based interventions.

Dyadic interventions

Literature reviews have found that psychosocial interventions such as stress management training and social support may positively impact psychological difficulties and QOL for people with dementia and their caregivers and delay residential home placement (e.g. Brodarty, Green, & Koschera, 2003; Van’t Leven et al., 2013). These interventions can be delivered to the person with dementia and caregiver separately or jointly. It has been suggested that joint interventions and incorporating social components may be more effective (Brodarty et al., 2003; Cooke, McNally, Mulligan, Harrison, & Newman, 2001). Some research has also investigated the impact of dyadic arts-based interventions, delivered to both the person with dementia and caregiver jointly. It is possible that dyadic interventions provide a connectedness to others close to the person with dementia and allow them to express and
connect with their identity ("who you are") both as an individual and in other roles (e.g. as a husband/wife/mother) which were reported to be important aspects of music interventions in McDermott et al.’s model (2014). Also, removing “excess disability” may have positive effects on the relationship between the person with dementia and their caregiver. This may reduce feelings of caregiver burden (through observing the person with dementia’s sense of mastery and achievement) and provide an enjoyable activity that both can engage in equally and experience shared enjoyment, important in “couplehood” (Hellström et al., 2005; Macpherson et al., 2009). These processes may have positive influences on the person with dementia, their caregiver and the relationship between the two.

**Rationale for current review**

There have been many research studies and reviews of the impact of arts-based interventions on people with dementia. The majority have focused on music-based interventions and found positive effects on mood, behavioural disturbances and BPSD (McDermott et al., 2013; Raglio et al., 2012), although a recent Cochrane review only found evidence for positive effects on depression (van der Steen et al., 2017). Research into visual arts interventions has found positive effects on self-esteem, QOL and wellbeing (Beard, 2012) and literary arts interventions have been shown to reduce BPSD’s and increase positive affect (Billington et al., 2013; Phillips et al., 2010). These studies have focused on interventions delivered solely to the person with dementia rather than as a dyad. One recent review has looked at the influence of dyadic psychosocial interventions including psycho-education and art viewing in seven studies (Rausch, Caljouw, & van der Ploeg, 2017). Dyadic arts-based interventions were reported to have positive effects on qualitative measures but no significant differences were found on quantitative measures. The authors concluded that there is a need to develop more interventions focusing on the needs of the dyad. No currently published reviews have solely reviewed the influence of dyadic arts-based interventions on
psychological outcomes. This review will therefore seek to answer the following question: Are dyadic arts-based interventions shown to influence psychological outcomes in people living with a dementia and their informal caregivers?

**Methodology**

A systematised literature review (Grant & Booth, 2009) was conducted to examine research on the psychological influence of dyadic arts interventions for people with a dementia and their informal caregivers.

**Definition of terms**

In this review, influence on psychological outcomes refers to any reported or observed effects on emotions, wellbeing, QOL or behaviour. Dyadic arts interventions refer to any activity using a form of the arts which is participated in simultaneously by both a person with a dementia and their informal caregiver. The definition of informal caregiver used is “persons without formal health care education who are caring for, or helping, a person with functional disabilities, prolonged psychiatric or physical illness, or age-related problems” (Lethin, 2016, p. 16). Most often, informal caregivers are family members (e.g. spouses, adult children) and friends.

**Literature search**

The electronic databases PsychINFO, Medline, Web of Science (Core Collection) and ASSIA were searched in February 2018 to identify studies relevant to the review. Further searches were conducted on Google Scholar and hand-searching of reference lists of relevant articles. Search terms covered three main areas of arts-based interventions, performing arts, visual arts and literary arts; Boolean operators ‘AND’ and ‘OR’ were used to combine search terms (see Table 1 for search terms and database results). Articles were screened for relevance by title and then by abstract before retrieving full texts, see Figure 1 for flowchart
showing search process. Inclusion and exclusion criteria for screening papers can be seen in Table 2. Papers including formal (paid) caregivers were not included due to the differing relationships between people with dementia and their informal and formal caregivers. Interventions conducted in residential settings were also not included due to the different caring responsibilities of family caregivers in the community. Papers were also excluded if the intervention was not solely arts-based as it would be difficult to determine the influence of the arts intervention. Dance and other exercise-based interventions were excluded due to the overlap with the psychological impact of physical exercise (Thuné-Boyle, Iliffe, Cerga-Pashoja, Lowery, & Warner, 2012). Twelve studies met the inclusion criteria (Table 3). Of these studies, seven were visual arts interventions and five were performing arts (no literary arts intervention studies met the inclusion criteria for this review). Three studies were quantitative in design, five were mixed methods and four qualitative.

Data extraction and analysis

The quality of papers was reviewed using the quality assessment criteria developed by Kmet, Lee and Cook (2004) as this was applicable to a range of study designs. The criteria and full scoring for quantitative and qualitative studies can be seen in Appendices A and B, with summary scores in Table 3. Mixed methods studies have been scored using both quantitative and qualitative criteria.

Structure of review

The literature search identified studies measuring the influence of performing arts and visual arts, therefore this is reflected in the structure of this review. Study findings are summarised under each type of arts intervention before considering the methodological limitations across the areas of literature. Finally, the clinical and research implications of the
review are considered. Only findings related to psychological outcomes will be included due to the scope of this review.

Results

Performing arts

All five studies measuring the impact of dyadic performing arts interventions focused on group singing interventions. Three studies measured the effects of time-limited, multi-session singing groups (Camic, Williams, & Meeten, 2013; Davidson & Almeida, 2014), one of which culminated in a concert performance (Mittelman & Papayannopoulou, 2018). One study focused on participants from on-going, multi-session groups (Osman, Tischler, & Schneider, 2016) and the final study recruited participants from a range of five different groups including both on-going and time-limited (Unadkat, Camic, & Vella-Burrows, 2017).

Three studies used quantitative measures; one solely quantitative study (Davidson & Almeida, 2014) and two mixed methods (Camic et al., 2013; Mittelman & Papayannopoulou, 2018) and the findings were mixed. Whilst Camic et al. (2013) found a significant increase in depression and no change in QOL for people with dementia following the group, this was in the context of slightly deteriorated scores on cognition and activities of daily living assessments. In contrast, the remaining two studies found significantly positive improvements in QOL and communication with the caregiver (Mittelman & Papayannopoulou, 2018) and lucidity (Davidson & Almeida, 2014) with additional benefit found from attending multiple sessions, with significant improvements in lucidity, mood and level of focus.

For caregivers, the quantitative findings were generally positive, with significant improvements in mood, relaxation (Davidson & Almeida, 2014) and self-esteem (Mittelman & Papayannopoulou, 2018). Davidson and Almeida (2014) commented that some of the lack of significant findings may have been due to a small sample size. However, the quantitative findings were also mixed, as one study reported no change in depression scores (Mittelman & Papayannopoulou, 2018). One study also reported no change in QOL, although this may have
been due to the relatively high levels of QOL rated throughout the study (Camic et al., 2013). Although, not significant, Camic et al. also reported an increase in stress levels whilst Davidson and Almeida found that they decreased. Again, this may have been due to the deterioration in cognitive scores and decrease in ADLs for people with dementia. Although it is difficult to conclude whether people’s cognition deteriorated similarly in Davidson and Almeida’s study as they did not include measures of cognitive ability, they did report an increase in caregiver-rated lucidity and focus which may suggest that their abilities remained stable throughout the study period.

All five studies included a form of qualitative information, although two did not use formal qualitative analysis (Davidson & Almeida, 2014; Mittelman & Papayannopoulou, 2018). All studies included reports of the positive impact of the activity of singing and doing so in a social/group setting with other people with dementia and their caregivers. Three studies each highlighted other important parts of the singing group experience including the accessibility of singing for all members (Camic et al., 2013; Osman et al., 2016; Unadkat et al., 2017), that it was a shared experience between the person with dementia and caregiver (Davidson & Almeida, 2014; Osman et al., 2016; Unadkat et al., 2017), enjoying the challenge of learning new songs and facilitator skills and characteristics (Camic et al., 2013; Mittelman & Papayannopoulou, 2018; Unadkat et al., 2017). Participants in one study also reported gaining enjoyment from singing familiar songs that facilitated reminiscence (Osman et al., 2016). All five studies included comments relating to improved mood or wellbeing and three commented on the extended impact, both in terms of mood (Mittelman & Papayannopoulou, 2018) and the enjoyment of singing at home (Camic et al., 2013; Mittelman & Papayannopoulou, 2018; Unadkat et al., 2017). Two studies highlighted how singing groups helped develop the person with dementia’s identity outside that of someone with a diagnosis (Davidson & Almeida, 2014; Unadkat et al., 2017). Only two studies
reported neutral or negative comments regarding participation in the group. These included some caregivers reporting initial apprehensiveness about attending, no effect on themselves but effects on the person they care for, and difficulties with relaxation due to concerns about the person with dementia (Camic et al., 2013; Davidson & Almeida, 2014).

**Methodological critique of the literature.**

With the exception of the qualitative aspects of Mittelman and Papayannopoulou’s (2018) mixed methods pilot study, all of the performing arts intervention papers reviewed were good quality (> 75%) according to the Kmet criteria (Kmet et al., 2004; Table 3). Overall, the papers included clear and well-defined objectives and results, and the conclusions were supported by the findings. Nevertheless, there were methodological limitations across the literature.

**Study design.**

Although well described, all three studies using quantitative methods were either exploratory or pilot studies with small sample sizes (ranging from 12 to 22) (Camic et al., 2013; Davidson & Almeida, 2014; Mittelman & Papayannopoulou, 2018). Whilst these were appropriate sample sizes for the designs, it is difficult to draw firm conclusions about the impact of the interventions. Positively, where relevant, changes to the number of participants due to their unavailability was reported. Also, no control groups with community participants were used, reducing the ability to determine causality. The study designs were clear and well described in qualitative studies.

**Sampling strategy.**

All studies described the sample that participants were recruited from, with one recruiting from a community mental health service (Camic et al., 2013) and the remaining studies from existing singing groups. Unadkat et al. (2017) included participants from five
different types of singing groups which increased the reliability of the findings but there was less information reported about the content and context of the groups. Three studies scored “partially” on the sampling strategy criteria due to insufficient sampling description (Camic et al., 2013; Davidson & Almeida, 2014; Mittelman & Papayannopoulou, 2018). These studies did not fully describe how participants were recruited (e.g. volunteer sampling) therefore it is unclear if some members of the target population were more likely to be recruited than others and it is difficult to evaluate possible sampling bias.

**Participant characteristics.**

Four studies reported limited data on participant characteristics including minimal demographic information about caregivers (Camic et al., 2013) and no reporting of gender for people with dementia (Davidson & Almeida, 2014) or type of dementia diagnosis (Davidson & Almeida, 2014; Mittelman & Papayannopoulou, 2018; Osman et al., 2016). This reduces the replicability of the studies and ability to generalise findings, however specific dementia diagnosis is not often sought in community arts-based interventions. Information that was relatively well reported included stage of dementia/level of impairment and relationship between the caregiver and person with dementia. Most caregivers were spouses, with smaller numbers of adult children participating and one “close friend” (Mittelman & Papayannopoulou, 2018). The majority of studies included people with mild to moderate dementia, with two studies including some participants with severe dementia (Camic et al., 2013; Unadkat et al., 2017). Whilst the tendency to include spousal caregivers and those with mild-moderate dementia may reduce the applicability of findings to other caregivers and those with more advanced dementia, it may also be reflective of the demographic living in the community (Lewis et al., 2014). All studies took place in Western countries, three in the UK and one each in the USA (Mittelman & Papayannopoulou, 2018) and Australia (Davidson &
Almeida, 2014). These findings, therefore, may not be applicable in other countries with different socio-economic populations and cultures.

**Outcome measures.**

Quantitative outcome measures were well defined and reported, however a range of psychological measures were used across the studies including mood, QOL, stress, anxiety and self-esteem. Whilst these may all be related constructs, it makes it more difficult to compare study findings and to compare interventions.

**Data analysis.**

The studies using quantitative data all used parametric t-tests, however none commented on whether the sample was normally distributed (Camic et al., 2013; Davidson & Almeida, 2014; Mittelman & Papayannopoulou, 2018). If the data were not normally distributed but parametric tests were used, this increases the likelihood of Type 2 errors. Mittelman and Papayannopoulou also used p < .1 as their significance value rather than p < .05. Although the justification for this was given as the small sample size, it may also increase the likelihood of a Type 1 error. Davidson and Almeida did not report the variance of scores including the mean and standard deviation, meaning that the distribution of scores could not be evaluated. One mixed methods study reported using “informal thematic analysis” (Mittelman & Papayannopoulou, 2018) but included very little description of the method of analysis and the development of codes and themes, as did Osman et al. (2016) in their qualitative study. This makes it difficult to assess their analysis. Positively, all studies included a form of qualitative information from participants, gaining more in-depth information about their experiences.
Verification and reflexivity.

Positively, four studies reported verification methods for qualitative data analysis (e.g. inter-rater reliability), however one did not (Mittelman & Papayannopoulou, 2018). This study also based the findings on only one researcher’s notes therefore it is unclear whether the themes would have been verified by others. Unadkat et al. (2017) explicitly discussed the possible impact of their own preconceptions on the qualitative data analysis and ways that this was minimised. The remaining three studies using a form of qualitative analysis (thematic analysis and “informal thematic analysis”), did not comment on the possible impact of their own preconceptions, therefore it is not clear that they were considered throughout the study (Camic et al., 2013; Mittelman & Papayannopoulou, 2018; Osman et al., 2016).

Visual arts

Five of the seven visual arts interventions assessed the impact of a combination of gallery/museum art-viewing and art-making (Camic, Tischler, & Pearman, 2014; Camic, Baker, & Tischler, 2016; Eekelaar, Camic, & Springham, 2012; Flatt et al., 2015; Schall, Tesky, Adams, & Pantel, 2017) and two assessed art-viewing with object handling (Johnson, Culverwell, Hulbert, Robertson, & Camic, 2017; McGuigan, Legget, & Horsburgh, 2015). Two studies used single-session interventions (Flatt et al., 2015; Johnson et al., 2017) and the remaining five used multiple sessions. Three studies used quantitative measures of psychological functioning, one mixed methods study (Camic et al., 2014) and two solely quantitative (Johnson et al., 2017), one of which was a randomised controlled design (Schall et al., 2017). Overall, the findings were mostly positive. Camic et al. (2014) reported no significant differences on measures of caregiver burden, QOL or activities of daily living for people with dementia. These non-significant results may have been affected by a small sample size. They also found no site-specific differences between a Georgian period art
gallery with mostly 17th and 18th paintings and a contemporary gallery with conceptual and abstract art. Johnson et al. (2017) used a crossover design to control for the order of art-viewing and object-handling activities. They found a significant increase in wellbeing for people with dementia and their caregivers following both activities which was not affected by the order of activity. Also, there was not a significant increase in wellbeing following the refreshment break, suggesting that the findings were related to the art activities rather than only group participation. Schall et al. (2017) also found significant improvements in wellbeing, QOL and apathy for people with dementia following art-viewing and art-making activities. In this study, the wait-list control group took part in independent museum visits and also reported significant improvements in apathy. This may suggest that engagement with museum environments has an impact on apathy regardless of format. When both groups had participated in the art intervention programme, the groups were combined and there were significant pre- post- decreases in overall neuropsychiatric symptoms, apathy and negative affect (depression and anxiety). These positive findings regarding wellbeing and emotional state were also confirmed in caregiver questionnaires.

All five studies reporting qualitative analysis described the positive impact of socialising with others and reduced isolation and four further papers also reported positive effects of its dyadic nature and sharing positive experiences (Camic et al., 2014; Camic et al., 2016; Eekelaar et al., 2012; McGuigan et al., 2015). Enjoyment of the programme was reported in all studies as well as positive effects on affect in two studies (Camic et al., 2016; Eekelaar et al., 2012) and self-esteem in one (Flatt et al., 2015). The art activities themselves were highlighted as important aspects in all papers, both through new learning and stimulation and the accessibility of the intervention, creating a sense of normalcy and changing perceptions about abilities. This was supported by McGuigan et al. (2015) who found consistently high levels of attention during the sessions, suggesting that people with
dementia can engage in visual arts sessions. Three papers also reported an increase in reminiscence by the people with dementia during the interventions (Eekelaar et al., 2012; Flatt et al., 2015; McGuigan et al., 2015). Two papers highlighted the importance of the gallery setting (Camic et al., 2014; Camic et al., 2016) and facilitator characteristics as valued aspects of the intervention (Camic et al., 2016; Flatt et al., 2015). Although no negative effects were reported, some commented that they were disappointed that the intervention was time-limited (Camic et al., 2016; Eekelaar et al., 2012) and others, conversely, that it would be difficult to continue the sessions long-term due to caregiving responsibilities (Camic et al., 2016). There were few reports of an extended effect after the sessions, with two studies highlighting caregiver-reported post-session cognitive benefits (Camic et al., 2014; McGuigan et al., 2015) and three reporting an intention to continue with visual art activities after the intervention (Camic et al., 2014; Camic et al., 2016; Eekelaar et al., 2012). Themes and quantitative outcomes did not appear to differ between the object handling and art-making interventions.

Methodological critique of the literature.

All visual arts studies reviewed were rated as good quality (> 75%) using the Kmet criteria (Kmet et al., 2004) (Table 3). The papers generally contained well-defined objectives, results and conclusions, outcome measures were clear and data verification strategies were described in all qualitative studies. However, some limitations of methodologies are described below.

Study design.

Designs were clearly described in all studies. Johnson et al. (2017) used a crossover design and found no change following a refreshment break, increasing the likelihood that improvements were due to the art activities. Positively, an RCT study included a wait-list
control group (Schall et al., 2017), however the general lack of control groups in study
designs reduces the ability to determine causality.

Sample sizes for the three studies using quantitative data to assess psychological outcomes were varied (ranging from 24 to 88), with one study including a relatively small number of participants (Camic et al., 2014). Two further studies also used quantitative data however these did not measure psychological outcomes and the sample sizes were small (12 and 15) (Eekelaar et al., 2012; McGuigan et al., 2015). Except for Eekelaar et al. the other studies with small sample sizes were not exploratory or pilot studies. Only Johnson et al. (2017) reported power analyses to determine sample size, finding that the sample size was adequate for the within-subject comparisons. However, the authors reported that the non-significant findings for the between-subjects analysis on the effect of activity order may have been underpowered. The seldom use of power calculations and the small sample sizes makes it difficult to determine whether the studies were sufficiently powered. The unavailability of participants at some sessions further reduced sample sizes; in one study this meant that only one dyad attended all three sessions (Eekelaar et al., 2012), reducing the generalisability of findings.

**Sampling strategy.**

All studies described the recruitment settings, however three studies scored partially on this criterion due to insufficient description of sampling methods (Camic et al., 2014; Eekelaar et al., 2012; Flatt et al., 2015). For example, it is unclear whether some participants in the target populations were more likely to be selected than others. Some studies recruited participants from specific populations (e.g. Johnson et al., 2017 recruited from a post-diagnostic memory support group and Eekelaar et al., 2012 from a community mental health service), which may limit the generalisability of findings.
Participant characteristics.

Three studies did not report specific dementia diagnoses (Camic et al., 2014; Camic et al., 2016; Eekelaar et al., 2012) but it is unusual for a specific dementia diagnosis to be sought in arts-based activities occurring in community settings. Two studies did not report the gender of people with dementia or specific caregiver characteristics (Camic et al., 2014; Camic et al., 2016). Most studies that reported the gender of participants had similar numbers of males and females in the study samples, with the exception of Johnson et al. (2017) who had a greater number of male people with dementia and female caregivers. These limitations may reduce the replicability and generalisability of findings. Positively, five studies reported the relationship between the caregiver and person with dementia; most caregivers were spouses, followed by adult children. Participant ages were relatively well reported as were stage of dementia/levels of impairment, with all participants in the early to mid-stages of dementia or with mild to moderate impairment. These levels of impairment and the primary inclusion of spousal caregivers are likely to be reflective of those living with dementia in the community (Lewis et al., 2014). All studies were conducted in Western countries, with four in the UK and one each conducted in the USA (Flatt et al., 2015), New Zealand (McGuigan et al., 2015) and Germany (Schall et al., 2017). Therefore, the findings may not be generalisable to other countries with different ethnic and socio-economic groups.

Outcome measures.

Although the use of quantitative outcome measures was well described, there was a range used across the studies making it difficult to compare between them. Two studies included measures of QOL with the people with dementia (Camic et al., 2014; Schall et al., 2017) and two used measures of wellbeing (Johnson et al., 2017; Schall et al., 2017), however in both cases they used different scales, reducing the possibility to make direct
comparisons. Other outcomes included cognition, depression, neuropsychiatric symptoms, caregiver burden and activities of daily living. For caregivers, only caregiver burden and wellbeing were measured in one study each (Camic et al., 2014; Johnson et al., 2017). The findings suggested that the interventions had positive outcomes for caregivers but this is only based on two studies.

**Data collection and analysis.**

The description of qualitative data collection methods was limited in two studies due to minimal information being available about interview questions or topics (Camic et al., 2016; Eekelaar et al., 2012), contrastingly Flatt et al. (2015) included a good example of a focus group script. Eekelaar et al. also did not include very detailed description of how the themes were developed. Although McGuigan et al. (2015) included an adequate description of data analysis, few quotes were included to illustrate the themes, making it more difficult to link the data with the theory. In Camic et al., (2014), only themes reported by all participants were included in the final themes. Whilst this increased the validity of findings, it may also have omitted identifying important, but not universal, experiences. Quantitative analysis methods were generally well described, however Schall et al. (2017) did not appear to account for multiple statistical analyses (e.g. Bonferroni correction) which may increase the likelihood of Type 1 errors in this study, for example, five t-tests were conducted on the Neuropsychiatric Inventory data. Also, McGuigan et al. did not report variance in their analysis, meaning that the distribution of scores could not be evaluated.

**Conclusions.**

In six studies, the conclusions drawn appear to be supported by the results. However, in one study (McGuigan et al., 2015), one conclusion drawn was that the results “strongly suggest… that future sessions should include objects and images to maximize engagement”
as this appeared to produce the highest attention levels (p. 268). Although this may have been an effective intervention, the absence of a control group and statistical testing and the small sample size makes it difficult to draw such strong conclusions. In addition, they also included a limited description of the content of intervention sessions, making it difficult to attribute any differences to particular interventions and not to other factors (e.g. different facilitators).

**Reflexivity.**

Only one of the papers utilizing qualitative components scored 2/2 on the reflexivity criterion (Kmet et al., 2004) (Camic et al., 2016). The remaining studies either contained no reference to the consideration of possible researcher preconceptions (Eekelaar et al., 2012; Flatt et al., 2015; McGuigan et al., 2015) or referred to reflexivity in the study design but did not explicitly consider the impact of potential preconceptions (Camic et al., 2014). As a result of this, the possible influence of the authors assumptions on data analysis is unknown.

**Discussion**

Some previous research has found positive effects of performing and visual arts on mood, self-esteem, wellbeing, QOL and BPSD for people with dementia when provided solely to this group (Beard, 2012; Kinney & Rentz, 2005; McDermott et al., 2013; Raglio et al., 2012; Rentz, 2002; Windle et al., 2017). However, there has also recently been a focus on interventions provided jointly to both the person with dementia and their caregiver. The aim of this paper was to review the literature on the influence of dyadic arts-based interventions on psychological outcomes for people with dementia and their informal caregivers. Overall the findings appeared generally positive, supporting previous research, but it is difficult to draw firm conclusions given the methodological limitations and the small number of studies available. Despite these limitations, the methodological quality of studies was high using the
Kmet criteria (>75%; Kmet et al., 2004), with only one study scoring below this for its qualitative component (Mittelman & Papayannopoulou, 2018).

Quantitative results suggested that people with dementia were able to engage in group singing interventions and that they may have a positive influence on QOL and communication with the caregiver. Camic et al. (2013) found a significant increase in depression and stable QOL in the context of subtle cognitive decline, therefore future research should consider measuring cognition alongside other quantitative measures to assess psychological outcomes relative to cognitive deterioration. For caregivers, the quantitative findings were generally positive, with significant improvements in mood and self-esteem. Although some studies reported no change in depression scores or QOL (Camic et al., 2013; Mittelman & Papayannopoulou, 2018). It is possible that some of the lack of change on these measures was related to the cognitive deterioration experienced by people with dementia (evidenced by Camic et al., 2013), therefore this should be considered in future research with dyad relationships.

Qualitative findings of the influence of group singing included improved mood and wellbeing, and a positive impact on the person with dementia’s identity beyond that of someone with the diagnosis. In some cases, it was reported that there was a longer lasting impact of the group in terms of mood and continuing singing activities at home (Camic et al., 2013; Mittelman & Papayannopoulou, 2018; Unadkat et al., 2017). Important contributing factors to the positive influence of interventions included the activity of singing, the group setting in reducing isolation, the dyadic nature of the activity and enjoyment in learning new skills and information. Facilitator characteristics were also noted as important in engaging participants and ensuring the group is accessible (e.g. Unadkat et al., 2017). Methodological limitations of this research included mostly small sample sizes, lack of control groups and limited demographic information. All studies were also conducted in affluent, Western
countries; therefore the findings may not be directly applicable to people in other societies. More detailed information on data collection and analysis methods and consideration of reflexivity is needed in qualitative research. In quantitative research, more consistent outcome measures are needed, as is clarity in the consideration of normality testing and sampling strategies.

Quantitative measures on the impact of visual arts interventions on people with dementia were slightly more conclusive, although this was based only on three studies. In two studies, significant increases in wellbeing were reported (Johnson et al., 2017; Schall et al., 2017) and other measures including QOL, affect and apathy significantly improved in one study (Schall et al., 2017). Contrastingly, one study found no change in QOL (Camic et al., 2014). For caregivers, only two studies used quantitative outcomes to measure the effects of visual arts, with one finding a significant increase in wellbeing, and another a trend for reduction in caregiver burden but no significant differences (Camic et al., 2014; Johnson et al., 2017).

Qualitative reports from people with dementia and caregivers highlighted similar findings to the performing arts literature in the importance of socialising in the group, its dyadic nature and enjoyment of new learning. In all studies, participants also reported enjoying the visual arts-based activity. Some qualitative findings also highlighted the effects of the intervention on affect, self-esteem and changing perceptions about people with dementia’s abilities through their engagement in the sessions (e.g. Camic et al., 2016; Flatt et al., 2015). The longer lasting impact of the group was also reported in some studies in terms of cognitive benefits for the person with dementia and a desire to continue with similar activities (Camic et al., 2014; McGuigan et al., 2015). Additionally, some qualitative visual arts studies also noted the importance of the gallery setting (Camic et al., 2014; Camic et al., 2016). Methodologically, similar limitations were noted as in the performing arts studies,
including limited information on sampling methods, demographics, qualitative data collection and explicit reflexivity. Also, the studies were conducted in Westernized countries with those with mild to moderate dementia, possibly limiting the applicability of findings to other countries. The visual arts literature did include two studies with larger sample sizes, one with a control group and another using a crossover design, however further research using larger samples and control groups is needed. Unlike the performing arts literature, there was a very limited number of quantitative outcome measures used with caregivers.

**Clinical implications**

With the lack of medications to cure or substantially slow the progression of dementia and the potential for negative impacts on psychological functioning, there is a great need for interventions to improve the quality of life in people with dementia and their caregivers. The increase in the number of people living with dementia in the community and the high demand on health and social care services increases the need for alternative ways of improving wellbeing and mental health. There is also a need for interventions not only provided for the person with dementia but also caregivers who can also experience lower levels of quality of life (Pinquart & Sörensen, 2003).

Although quantitative outcomes were mixed, performing and visual arts interventions can tentatively be linked with improved psychological outcomes for people with dementia and their caregivers as supported by qualitative findings. Engagement in group dyadic arts-interventions was associated with improved wellbeing, QOL, communication with the caregiver, self-esteem and mood (Davidson & Almeida, 2014; Johnson et al., 2017; Mittelman & Papayannopoulou, 2018; Schall et al., 2017). The accessibility, high engagement and new learning aspects of the group may have led to the increased self-esteem and positive effects on the identity of the person with dementia and changes in the way they
are seen by others. The group nature of the interventions facilitated decreased isolation and a sense of community with others experiencing the same challenges. The significant increase in communication from people with dementia towards caregivers in one study may also have been facilitated by the dyadic nature of the group. This may be due to the activities facilitating a sense of mastery and achievement for both the person with dementia and caregiver and removing “excess disability”, increasing communication between those present (Macpherson et al., 2009). This positive impact of the dyadic aspect of the group was highlighted in six of the twelve studies reviewed and may indicate that the interventions provided a shared activity promoting ‘couplehood’ (Hellström et al., 2005). As the group was for both partners of the dyad and reported to be accessible, this may have had a positive influence on relationships and communication, facilitating a sense of reciprocity (Merrick et al., 2016). It may also have allowed people with dementia to connect with their identity (“who you are”) and with others (both dyadically and more generally) in the “here and now”, highlighted as important processes in the psychosocial model of music in dementia (McDermott et al., 2014). Although further, additional research is needed in order to routinely suggest recommending dyadic arts-interventions in standard care, clinicians can now consider these as community-based activities that could be beneficial to dyads, particularly those who are socially isolated, have lower QOL or wellbeing or have mood difficulties.

Research implications

It is important to note that research into arts and dementia is in the early stages and remains poorly funded. Due to the methodological limitations of current literature, the conclusions that can be drawn about the impact of dyadic arts-based interventions on people with dementia and their caregivers is limited. The findings suggest that further research is warranted to investigate these links. Similar to recommendations from previous reviews,
future studies should utilise larger sample sizes and control groups wherever possible, to determine if there is a causal relationship (Kinney & Rentz, 2005; Rausch et al., 2017; van der Steen et al., 2017). If feasible, future research should include more detailed demographic information (e.g. dementia diagnoses) as also concluded by Rentz (2002), however it is important to note that community arts-based programmes do not routinely seek this information. The existing research associates choral singing and visual arts interventions with increased wellbeing, QOL, improved mood and decreased isolation, however the range of outcome measures makes findings difficult to compare. Therefore, further research with consistent outcome measures is necessary, supporting recommendations by Beard (2012) and van der Steen et al. (2017) that consistency is needed in outcome measures and that “process” measures (e.g. wellbeing and QOL), rather than clinical, medical focused measures are preferred. It may also be helpful to include measures of the dyadic relationship in future studies to assess any impact of dyadic group singing on aspects of the relationship e.g. satisfaction. The most common design used was mixed methods, allowing researchers to gain further insight into participant’s experiences of interventions and factors contributing to quantitatively-measured changes on psychological outcomes. Qualitative findings supported the positive experience of participating in arts-based activities for both people with dementia and caregivers in all studies. Due to the inconsistent findings on quantitative measures, it is important for future research to consider other quantitative methods to be used alongside qualitative measures in further mixed methods studies. McDermott et al. (2013) also highlighted the need to find quantitative measures that are sensitive to change, as effects of interventions may be short-lived due to cognitive impairment. They also noted that interventions are still worthwhile if they improve QOL, even if the effects are temporary. Johnson et al., (2017) supported this recommendation by providing evidence for the use of a brief wellbeing measure. Positively, this review suggests that research is focusing on the
impacts of arts-based interventions on people with early to mid-stages of dementia living in the community and their caregivers, previously highlighted as areas lacking in arts-based research (Beard, 2012).

**Conclusion**

The aim of this review was to evaluate the literature on the influence of dyadic arts-based interventions on psychological outcomes for those with dementia and their informal caregivers. This review tentatively links arts interventions with improved outcomes, as seen in some increases in QOL, wellbeing and mood on quantitative measures. These positive effects were validated through qualitative data. In all studies participants reported enjoyment from engaging in the interventions and in some studies, participants reported increased wellbeing and self-esteem, improved mood and positive effects on the identity of the person with dementia. Aspects of the interventions reported to have a positive impact on participants included the activity itself (either choral singing or visual arts), both the group and dyadic nature of the sessions and learning new skills. In some studies, the longer lasting impact of the intervention was noted, both on psychological outcomes and continuing the shared activity after the study. However, more firm conclusions about the impact of the interventions are difficult to draw due to methodological limitations. Clinical and research implications have been discussed and future research should aim to improve on the methodological issues discussed in this review.

An exploratory investigation into the relationship between choral singing, stress and wellbeing in people with a dementia and their caregivers

Word count: 7922 (878)

Philippa Bourne BSc (Hons)

For submission to Dementia: The International Journal of Social Research and Practice
Abstract

Background: In recent years, evidence for the positive effects of singing with people with dementia has been promising. Some research has used physiological measures to analyse the impact of singing, however this method has not before been used in a community study with people with dementia; this study explored the interactions between these areas of research.

Method: A mixed methods, quasi-experimental design was employed in this exploratory, within-subjects study. Physiological measures of stress (salivary cortisol and heart rate) and subjective measures of wellbeing and stress were obtained during a choral singing group from 17 participants, 10 with a dementia and 7 caregivers. Data were also collected during a non-singing control condition. Interviews investigating the influence of the singing group were conducted with caregivers and analysed using thematic analysis.

Results: Quantitative results showed positive effects of group singing on composite wellbeing, happiness and optimism. Stress hormone results were mixed. Heart rate variability significantly increased for people with dementia which may be associated with the significant increase in happiness, as shown in previous research. Qualitatively, group singing was overall reported to have a positive influence on people with dementia and caregivers. These influences included effects on mood and cognition, and positive aspects of the intervention were described.

Conclusions: The findings suggest that additional research is warranted to further investigate interactions of physiological and psychological variables related to choral singing in people with a dementia. Methodological difficulties of saliva collection with this population need to be addressed if stress hormones are used in future research.

Keywords: dementia, choral singing, wellbeing, stress, physiological measures
Introduction

The dementias

The dementias are progressive neurodegenerative conditions that cause brain cell loss and affect cognitive, behavioural and emotional functioning. It has been estimated that there are 850,000 people living with dementia in the UK (Prince et al., 2014). The onset of dementia is most commonly in later life and, as the population over 60 in the UK increases and with better awareness and diagnostic abilities, the rate of dementia diagnosis is also increasing (Lewis, Karlsberg Schaffer, Sussex, O’Neill, & Cockcroft, 2014). As well as impacting the person with dementia and their family, the increase in rates of dementia also increases demands on health and social care services.

Different types of dementia have different effects on people’s functioning, the most commonly diagnosed are Alzheimer’s disease (AD), vascular dementia (VD), frontotemporal dementia (FTD) and dementia with Lewy bodies (DLB). Cognitive symptoms can include memory loss, difficulty producing or understanding language and loss of executive functions. Some forms of dementia can affect social functioning (e.g. using inappropriate language or behaving in ways deemed inappropriate by others). Emotional regulation and capacity to deal with stress can also be affected (Cheston, 1998). Alongside the symptoms outlined above, people may experience mental health difficulties and decreased wellbeing.

As impairment increases, greater assistance with activities of daily living is required, provided by informal caregivers (e.g. family members, friends), formal caregivers (e.g. agency care staff, residential care) or a combination of both. Whilst caring for a family member with dementia can be perceived positively by caregivers (e.g. maintaining closeness and gaining satisfaction; Pinquart & Sörensen, 2003), it can also be stressful. Caregivers experience higher levels of stress and lower levels of wellbeing than non-caregivers, this
difference increasing when the person cared for has dementia (Pinquart & Sörensen, 2003). High levels of “caregiver burden” are associated with lower quality of life for people with dementia and earlier residential care placement (Yaffe et al., 2002).

**Therapeutic use of music in dementia care**

Although there are currently no curative or disease-modifying treatments for any of the dementias, recommendations have been made for addressing symptoms associated with the disease. One recommended non-pharmacological intervention for non-cognitive symptoms (e.g. agitation and anxiety) is the “therapeutic use of music” (NICE, 2006, p. 29), based on moderate evidence that a randomised control trial of music therapy reduced wandering in nursing home residents (Groene, 1993; NICE, 2007). Earlier, Kitwood (1997) also highlighted the importance of providing person-centred activities, such as the arts, to enable people to feel a sense of purpose, identity and attachment to others. Music therapy and music interventions differ, in that music therapy is delivered by a qualified music therapist with specific therapeutic goals and music interventions do not necessarily have a music therapist present and have broader aims such as improving wellbeing (Petrovsky, Cacchione, & George, 2015). Both can take place individually or in a group and can consist of different activities e.g. singing, playing instruments and listening to music.

Most studies have found positive effects (particularly short term) of group singing on cognitive abilities (e.g. orientation and attention), psychological factors (e.g. stress, anxiety QOL and mood), and behaviour (e.g. agitation and aggression) in people with dementia (Bruer, Spitznagel, & Cloninger, 2007; Ledger & Baker, 2007; Mittelman & Papayannopoulou, 2018; Osman, Tischler, & Schneider, 2016; Raglio et al., 2008; Suzuki et al., 2004). Singing in a group can also decrease social isolation, something particularly of concern for people with a dementia (Camic, Williams, & Meeten, 2013). Two literature
reviews have also found positive effects of music as an intervention for people with dementia, including on mood and behavioural disturbances (McDermott, Crellin, Ridder, & Orrell, 2013) and behavioural and psychological symptoms of dementia (Raglio et al., 2012). Other studies however, have found inconclusive results or no change in quantitative measures following group singing (Petrovsky et al., 2015; Cooke, Moyle, Shum, Harrison, & Murfield, 2010) and methodological difficulties such as small sample sizes make conclusions difficult to draw (Vink, Bruinsma, & Scholten, 2003). Also, a recent Cochrane review concluded that although music interventions may have an impact on depressive symptoms for people with dementia, there was no conclusive evidence that they had an impact on wellbeing, QOL, anxiety or agitation, and the evidence was of low to medium quality (van der Steen et al., 2017). Therefore, it was recommended that future research should include larger sample sizes and “positive” outcome measures such as wellbeing and social factors. Although some evidence suggests that active music interventions have greater positive effects than receptive (e.g. group singing vs listening to music) (Sakamoto, Ando, & Tsutou, 2013), this has not been found consistently (Raglio et al., 2015) and further research is needed to investigate any differences.

Research has also investigated the impact of music and singing on dementia caregivers, particularly important in the context of caregiver burden and increased stress for this population. Singing groups attended by both caregivers and those with dementia have been found to improve wellbeing, mood and social inclusiveness, provide a sense of belonging for both groups and have a positive impact on their relationship (e.g. Davidson & Almeida, 2014; Osman et al., 2016; Unadkat, Camic, & Vella-Burrows, 2017). The provision of music-based interventions for the caregiver-cared for dyad has also been recommended in a systematic review of non-pharmacological interventions for people with dementia (Hulme, Wright, Crocker, Oluboyede, & House, 2010).
In the moment

Due to the deteriorating effects on memory of some dementias, the longer-term influence of interventions can be challenging to measure and understand fully due to difficulties with awareness of any impact and ability to recall and communicate this over time. Quantitative research with the dementias has begun to focus on short-term “in the moment” effects (e.g. Johnson, Culverwell, Hulbert, Robertson, & Camic, 2017; Petrovsky et al., 2015) based on interventions of up to two hours. The importance of this was highlighted by a caregiver when recalling the benefits of even short-term effects of art interventions on a family member, “you do it for the moment”, as well as in a recent literature review (MacPherson, Bird, Anderson, Davis, & Blair, 2009; McDermott et al., 2013).

Wellbeing in dementia

A consensus on the definition of wellbeing has not been reached, creating differences in its description and measurement between research studies. Wellbeing was originally based on theories of happiness and the ability to assimilate and accomplish one’s goals (Camic, Hulbert, & Kimmel, 2017). The difficulties in conceptualising wellbeing were considered by Dodge, Daly, Huyton and Sanders (2012) who proposed a new definition, combining aspects from previous theories. They defined stable wellbeing as “when individuals have the psychological, social and physical resources they need to meet a particular psychological, social and/or physical challenge” (p. 230). They depicted this as a “see-saw”, with wellbeing as the mid-point, impacted upon by life challenges on one side and the resources to cope with these challenges on the other.

Kitwood (1997) emphasised the importance of those with dementia retaining their “personhood” (related to high levels of wellbeing) and how this should be a key task in their care. Retaining personhood “involves enabling the exercise of choice, the use of abilities, the
expression of feelings, and living in the context of relationship” (Kitwood, 1997, p. 60). A NICE quality standard (2013) focused on the importance of improving wellbeing in dementia and recommended ways to facilitate this, including supporting people with attending leisure activities of their choice and creating and maintaining relationships. Evidence suggests that music and singing can have a positive impact on the wellbeing of both people with dementia and their caregivers (Osman et al., 2016; Unadkat et al., 2017).

**Measurement of stress**

Cohen, Kessler and Underwood-Gordon (1997) proposed a heuristic model of stress incorporating psychological, biological and environmental factors. The model describes how appraising an inability to manage environmental demands leads a person to perceive the situation as stressful, causing negative emotions. This is followed by physiological and behavioural responses which can increase the risk of physical illness and mental health difficulties. When a situation is perceived as stressful, the body enters an acute stress response, which includes the activation of the hypothalamic-pituitary-adrenocortical (HPA) axis and the release of the steroid hormone cortisol (Ulrich-Lai & Herman, 2009). One way that cortisol affects the body is to increase glucose production which prepares the body to react to stressful stimuli (Everly & Lating, 2013).

Psychological stress can be defined as “a relationship with the environment that the person appraises as significant for his or her wellbeing and in which the demands tax or exceed available coping resources” (Lazarus & Folkman, 1986, p. 63). The term stress is often used interchangeably with the term anxiety, defined as “a complex, affective, physiological and behavioural response system (i.e., threat mode) that is activated when anticipated events or circumstances are deemed to be highly aversive” (Clark & Beck, 2011, p. 5). Feelings of anxiety and perseverative cognitions (worry and rumination) can extend the
length of the temporary stress reaction (Brosschot, Gerin, & Thayer, 2006). The definition of stress used throughout this study is “a response characterized by physiological arousal and negative affect, especially anxiety” (Folkman, 2013).

Although previous research has not commented on the prevalence of high stress levels in people with dementia, reported estimates of anxiety prevalence vary from 5 to 70 percent and anxiety is one of the most common mental health difficulties in older adults with early stage dementia (Petrovsky et al., 2015). Increased stress and anxiety may be related to receiving a dementia diagnosis, difficulties with daily living and worries about the future; higher anxiety levels have been associated with increases in verbal aggression, wandering and likelihood of nursing home placement (Petrovsky et al., 2015).

Subjective measures (e.g. self-report questionnaires and interviews) are the most common methods of assessing stress. One way to measure stress objectively is using hormonal markers (e.g. cortisol levels) (Ice, 2005; Smyth, Hucklebridge, Thorn, Evans, & Clow, 2013). Cortisol levels have been used to examine the effects of music on stress in healthy populations and reductions have been found following low stress singing, concert attendance and group drumming interventions (Fancourt, Auffeger, & Williamon, 2015; Fancourt et al., 2016; Fancourt & Williamon, 2016). Research has also studied links between other hormones and stress levels including cortisone, testosterone, progesterone and dehydroepiandrosterone (DHEA) (Fancourt et al., 2015; Fancourt et al., 2016; Fancourt & Williamon, 2016). Like cortisol, cortisone is a glucocorticoid, a hormone released from the HPA axis during the stress response. Testosterone and progesterone are gonadocorticoids (sex steroid hormones) affected by the body’s stress response and DHEA is a steroid hormone involved in the body’s immune response (Fancourt & Williamon, 2016).
To date, there have been no published studies analysing the effect of group singing on cortisol levels as an indicator of stress in this population. A recent paper has recommended future research to investigate the effects of music on biomarkers in populations with different health conditions (Fancourt, 2014). Using physiological measures of stress may be particularly relevant in research studies with people with cognitive impairment, who may not be able to accurately remember or communicate their levels of stress e.g. those with advanced dementia.

As well as stress hormones, heart rate (HR) is another method of measuring the body’s physiological response. HR is controlled by the autonomic nervous system (ANS), which consists of two parts: the sympathetic nervous system (SNS) responsible for preparing the body for the fight-or-flight response and increasing HR, and the parasympathetic nervous system (PNS), responsible for rest, digestion and decreasing HR (McCrory, 2007). HR can be analysed crudely in mean changes in the number of beats per minute, or by analysing heart rate variability (HRV), the variation in the time interval between heartbeats (Shaffer, McCraty, & Zerr, 2014). HR data can be difficult to interpret as it can be affected by numerous factors including anxiety, excitement and exercise (Wilhelm, Pfaltz, Grossman, & Roth, 2006). However, evidence suggests HR is reliably influenced by stress (e.g. Zhai & Barreto, 2006), and different music tempi, with high tempo music increasing HR and low tempo reducing HR (Bernardi, Porta, & Sleight, 2006; Sandstrom & Russo, 2010). Healthy HRV indicates the body’s ability to respond to different situations, and low HRV is associated with a range of health problems (e.g. Tsuji et al., 1994). HR and HRV can be assessed using wearable sensors, however this is a relatively new area of research and further work is needed to understand their reliability and validity. Therefore, it is important to combine the use of these measures with self-report measures to aid interpretation.
CHORAL SINGING, DEMENTIA, STRESS AND WELLBEING

Research hypotheses and questions

1). Level of salivary cortisol will decrease following choral group singing and the decrease will be significantly greater than after a non-singing control condition for both PWD and caregivers;

2). Wellbeing levels will increase following choral group singing and the increase will be significantly greater than a control condition for both PWD and caregivers;

3). Subjective stress levels will decrease following choral group singing and the decrease will be significantly greater than a control condition for both PWD and caregivers;

4). Heart rate variability will be greater in the singing condition for both PWD and caregivers;

5). The following question guided the interviews: How does participating in choral singing influence the person with dementia and participating caregiver?

Method

Design

A mixed methods, quasi-experimental design was employed in this naturalistic, within-subjects, exploratory study integrating quantitative data from physiological measures and self-report questionnaires with qualitative interviews.

Participants

Participants were recruited from an existing weekly singing group which had been running for approximately two months and all attendees were invited to participate in both conditions (Table 1). Inclusion criteria: diagnosed with a mild to moderate dementia or the caregiver of an attending person, able to attend a singing group and ability to give consent. Sample size was pre-determined due to group membership therefore a G*Power sensitivity...
analysis was computed rather than *a priori* (Faul, Erdfelder, Buchner, & Lang, 2009). With an α score of .05, power of .80 and sample size of 20, the effect size $d_z$ is .59 meaning that this sample size would only detect significant differences if the effect size is $> .59$. Twenty people were approached and all but three consented to participate. Seventeen (10 people with dementia/7 caregivers) completed quantitative measures at the singing session and 13 (7 people with dementia/6 caregivers) at the control session. At the control session, one person with dementia (PWD) chose not to provide a saliva sample after the group, therefore there was paired salivary data for 12 participants. Interviews were conducted with seven caregivers. No participants reported taking immunosuppressant medications (which can affect hormone levels) (see Appendix J for a list of participants’ medications).

**Procedure**

**Singing session.**

Upon arrival, wristbands were fitted to participants’ dominant wrists, followed by collection of pre-measures of saliva, stress and wellbeing questionnaires. They also completed a demographic questionnaire (Appendix F). For saliva samples, participants placed swabs in their mouths and chewed for 60 seconds whilst holding onto the end to reduce the risk of swallowing the polymer roll. Once the chewing process was complete, they returned the swab to the tube, it was immediately sealed and the samples were placed on ice. Samples were frozen at -20°C for at least 3 weeks before analysis. The singing session then took place for the usual 60-minutes and was led by an experienced choral conductor and accompanied by a pianist. It began with a welcome song, initiated by the conductor as an indicator for group members to move to the two rows of seats as the session was starting, they also joined in with singing as they moved. Following this, participants engaged in physical (e.g. stretching) and vocal warmup exercises and sang three songs in both sitting and standing positions.

Range: 45-79

aDNC refers data not collected where PWD attended the group without a caregiver or caregivers participated in the study but the person they care for did not.

bAD – Alzheimer’s disease, FTD – Frontotemporal dementia, DLB – Dementia with Lewy bodies, Mixed dementia – Both AD and FTD
CHORAL SINGING, DEMENTIA, STRESS AND WELLBEING

The songs had previously been either partly or fully practised in previous sessions. The choral group focused on vocal production and technique as well as exploring repertoire from sea shanties to opera (Table 2). At the end of the session, saliva samples and questionnaires were again completed and Empatica® wristbands removed, followed by socialising and refreshments.

**Control condition.**

The within-subjects control condition consisted of art-viewing at a local gallery. Participants were previously invited to an exploratory session at the same venue two weeks before to familiarise themselves with the environment. The same data collection procedures were employed as in the singing session. The session was led by an experienced gallery educator who displayed PowerPoint slides of paintings, described the paintings’ history and engaged the group by asking questions. There were also three opportunities to stretch and move around. Fourteen paintings from the 17th and 18th centuries were shown in pairs and participants were asked to interpret and identify links between paintings. Visualisation techniques were also used (e.g. imagine you are in this scene, what can you hear/see/smell). The session lasted 60 minutes at the same time and day of the week as the singing session, four weeks later. Art-viewing as a control was chosen to account for group effects, facilitator expertise and similar levels of movement.

Interviews.

Semi-structured interviews were conducted with caregivers by phone within one week of the control session. The purpose of the interviews was to gain further insight into how the singing group was experienced by caregivers and their perception of how it was experienced by the person they care for (see Appendix I for interview schedule). Interviews were completed with all seven caregivers who consented to take part in the study, lasting between 8 and 26 minutes, depending on the level of detail given.

Measures

Subjective measures.

The Canterbury Wellbeing Scales (CWS; Appendix G; Johnson et al., 2017) are comprised of five vertical visual analogue scales (VAS) developed to measure subjective wellbeing in PWD. Each scale is numbered from 0-100 and participants are asked to mark how happy/sad, well/unwell, interested/bored, confident/not confident and optimistic/not optimistic they feel in the moment of completing the scales. A composite score of the sum of all scales is also calculated (0-500). The CWS have been used in previous studies and reliability analyses found good internal consistency (Camic et al., 2017; Johnson et al., 2017). Alongside the CWS, participants also completed a VAS stress scale (Appendix G; as described by Wewers & Lowe, 1990) to indicate their subjective stress levels in that moment (stressed/not stressed, 0-100). Lesage, Berjot and Deschamps (2012) found support for the interconcept and construct validity of VAS scales for measuring stress and concluded that they are “at least as discriminating as a questionnaire” when comparing two groups. Others have found that people with dementia use VAS scales “in a similar way to the general population” (Arons, Krabbe, van der Wilt, Olde Rikkert, & Adang, 2013). VAS scales were chosen as they are valid for use in within-subjects designs and can assess change over short
periods of time (Wewers & Lowe, 1990). They are reliable, brief and easy to administer, important considerations when assessing people with dementia (Camic et al., 2017; Wewers & Lowe, 1990).

**Saliva assays.**

Materials for saliva collection included the SalivaBio® Oral Swab, valid for measuring the hormones tested in this study (Salimetrics, 2017). Levels of five hormones (cortisol, cortisone, testosterone, progesterone and DHEA) were measured, all of which have previously been used as indicators of stress in research participants (Fancourt et al., 2014; Fancourt et al., 2015; Fancourt & Williamon, 2016).

**Heart rate variability.**

Wearable sensors were used to monitor continuous measurement of blood volume pulse (from which HRV can be derived). To explore the effects of group singing on HRV in this population, Empatica® (2017) wristbands were placed on each participant at the beginning of the session and removed following post-group measures. Detailed information on HRV data collection methods can be seen in Appendix H.

**Ethics**

Ethical approval for this study was obtained from a research ethics panel at Canterbury Christ Church University (Appendix C) and the study adhered to British Psychological Society guidance (2010). A vital ethical issue centred around obtaining informed consent, considering the cognitive impairment experienced by this population. Participants’ capacity to consent was considered during each process of obtaining consent and, where appropriate, a capacity assessment (Dewing, 2007) was completed beforehand. As the majority of PWD attended the group with a caregiver, consent was to be sought from them if there was uncertainty. Participants were initially informed about the study by the organisers of the choral programme.
and provided with information sheets (Appendix E). A researcher then attended a singing session to further explain the study and answer questions. All participants were deemed to have capacity to consent and gave informed written consent (Appendix D).

**Data analysis**

Quantitative analysis was completed using SPSS version 24. Initial interpretation of the data showed that it did not consistently meet the requirements of parametric data, therefore Wilcoxon signed-rank tests were used. Pearson’s r effect sizes were reported for all analyses (Fields, 2013). Pre- and post-session scores for the CWS, stress scale and stress hormone levels for PWD and caregivers were compared for both the intervention and control conditions. Change scores were also calculated by subtracting pre- scores from post- scores and were compared between sessions using Wilcoxon tests. Although data are reported separately for PWD and caregivers in this paper, analysis for all participants combined can be seen in Appendix L. Bonferroni-corrected significance levels were used for the CWS \( (a = .05 / 6 = .008) \) and HRV \( (a = .05 / 3 = .015) \) data to reduce the risk of Type 1 errors due to the use of multiple statistical tests (Bland & Altman, 1995).

Mean HRV scores were determined before, during and after both sessions. For the singing session, the before and after periods were 2 minutes 33 seconds immediately before and after the activity and for the control session, 3 minutes before and after. Data analysis used Wilcoxon signed-rank tests to compare mean HRV scores for the time periods before-during, during-after, before-after each session. The mean change in HRV between the time periods was also compared between the singing and control conditions using Wilcoxon signed-rank tests.

Interviews were analysed using thematic analysis based on Braun and Clarke’s (2006) six-stage approach (Figure 1).
Quality assurance

Subjective measures were scored “blind” to reduce researcher bias. Researchers and staff assisted in data collection, reducing the possibility of group members assisting one another and potentially biasing results. Saliva assays can be affected by a number of factors including eating or drinking within one hour of giving the sample and some medications (Salimetrics, 2015). Participants were therefore asked not to eat or drink anything except water in the hour prior to giving the saliva sample and medications were documented. During the thematic analysis, regular meetings with the first supervisor discussed codes and themes, which allowed for modification as needed. Twenty percent of these data were also reviewed by this supervisor. Throughout the project, a research diary was kept, supporting continuous reflection of personal interests and preconceptions that could inadvertently affect results (see Appendix M for example research diary extracts).

Results

Quantitative results

Initial analysis.

Following consultation with an expert in analysing saliva data, the data were cleaned to remove one outlier from the cortisol data. Examination of histograms (Appendix K) and significant results on Kolmogorov-Smirnov tests (Table 3) showed that some variables were not normally distributed, therefore, non-parametric equivalents were used for all analyses. These need to be interpreted with caution due to small sample sizes. Wilcoxon signed-rank tests were used to compare pre- and post- scores for the singing and control sessions and between activities.
1. Data was transcribed, read and re-read whilst noting down initial ideas.

2. Initial codes generated by hand and then transferred to NVivo Version 11 (QSR, 2015). 20% of codes reviewed by second researcher.

3. Broad themes created and codes organised under themes. Relevance to research question reviewed.

4. Themes reviewed and relevance of codes to each theme. Broad themes containing insufficient data collapsed or discarded.

5. Names, definitions of themes and links between themes clarified.

6. Report writing including relating to research question and links with quantitative data.

Note: *Significant results indicate data which significantly deviates from a normal distribution

**Stress VAS scale.**

Wilcoxon signed-rank tests (Table 4) were used to compare subjective stress levels. The stress scale was inversely scored, where a higher score indicated less stress. PWD reported a significant increase in stress following the control session with a large effect size (p = .027, r = -.59). Although not significant, scores decreased for both PWD and caregivers after the singing session and for caregivers after the control session (p > .05). When comparing the intervention and control sessions there were no significant differences (p > .05).

**CWS scales.**

Full details of the CWS analysis can be seen in Table 4. The Bonferroni-corrected significance level was .008 as there were six CWS analyses completed. Following the singing session, PWD showed significant increases on the composite, happiness and optimism scales with large effect sizes (p < .008, r = -.60 to -.63). Also of note, although not significant
following Bonferroni correction, PWD’s wellness scale (n = 10, p = .036, r = -.47) and caregivers’ composite wellbeing (n = 7, p = .028, r = -.59), happiness (n = 7, p = .028, r = -.36), wellness (n = 7, p = .046, r = -.53) and optimism (n = 7, p = .028, r = -.59) scores increased and were approaching significance. There were no significant differences on Wilcoxon signed-rank tests following the control session (p > .008), however the increase in optimism for caregivers was approaching significance (n = 6, p = .043, r = -.58). When comparing change in CWS scores between sessions, none of the analyses were significant (p > .008). However, the trend for a greater increase in happiness following the singing session was approaching significance for both groups with large effect sizes (PWD n = 7, p = .063, r = -.50; caregivers n = 6, p = .046, r = .57).

Saliva assays.

The sample size was further decreased when analysing the saliva samples. This was due to an insignificant amount of saliva in some vials. As a result, statistical analysis could not be completed on the progesterone and DHEA hormones. Wilcoxon signed-rank tests were performed on the remaining three hormones, cortisol, cortisone and testosterone; however, these should be interpreted with extreme caution as sample sizes ranged from n = 2 to n = 7 (Table 4). All caregivers showed a decrease in cortisone levels following the singing session, this difference was significant and had a large effect size (p = .043, r = -.64). None of the other hormone analyses following the singing session were significant. When the two groups were combined (Appendix L), the decrease in cortisol levels reached statistical significance, suggesting that a larger sample size may be needed in future studies.

In the control condition, none of the analyses were significant. When comparing the singing and control conditions, none of the analyses were significant. However, for caregivers, cortisol and cortisone levels showed a greater decrease following the singing
session compared to the control condition and, although these were not significantly different, they were approaching significance and had large effect sizes ($n = 4$, $p = .068$, $r = -.65$).

**Heart rate variability.**

Due to a device malfunction, data for one participant was not available; HRV analysis was based on 16 participants (9 PWD, 7 caregivers) at the singing session and 12 (6 PWD, 6 caregivers) at the control condition. Figure 2 shows HRV scores for both conditions, with the largest HRV score for PWD during the singing session and the smallest for caregivers before the control condition. For PWD, the before and after HRV scores appeared to be similar at the singing and control conditions but the during HRV scores appear to be quite different. For caregivers, there also appeared to be an increase in HRV during the singing session compared to the control session, with slightly higher HRV before and after the control session than the singing session and the least amount of change in HRV in the control condition. Wilcoxon signed-rank tests were used to compare the three time-periods with one another and then to compare these differences across the two sessions (Table 5).

When comparing HRV during the singing session to before and after, PWD had significantly more variability during the session compared to the other time periods. Although non-significant, caregiver scores also suggested more variability during the session compared to before ($n = 7$, $p = .018$, $r = -.63$) and after ($n = 7$, $p = .063$, $r = -.50$) as well as more variability after compared to before ($n = 7$, $p = .063$, $r = -.50$), which were approaching significance. In the control session, none of the analyses were significant ($p > .015$). When comparing HRV across the sessions, none of the analyses were significant ($p > .015$), although the difference between HRV during and after the control condition was approaching significance, with a greater difference at the control condition ($n = 6$, $p = .028$, $r = -.64$).
Summary of quantitative analyses.

In the context of the small sample sizes, these analyses need to be interpreted with caution, particularly the hormone data. Despite this, some trends and statistically significant differences were present. Overall, wellbeing significantly increased on the composite, happiness and optimism scales for PWD with large effect sizes and caregiver increases in composite wellbeing ($n = 7$, $p = .028$, $r = -.59$), happiness ($n = 7$, $p = .028$, $r = -.36$), wellness ($n = 7$, $p = .046$, $r = -.53$) and optimism ($n = 7$, $p = .028$, $r = -.59$) were approaching significance, as was wellness for PWD ($n = 10$, $p = .036$, $r = -.47$). Subjective and hormonal stress remained relatively stable, with a significant decrease in cortisone for caregivers following singing. Following the control session, PWD had a significant increase in self-reported stress and caregivers’ increase in optimism scores was approaching significance ($n = 6$, $p = .043$, $r = -.58$). When comparing the singing and control sessions, although the analyses were non-significant, some trends were approaching significance: a greater increase in happiness for both groups (PWD $n = 7$, $p = .063$, $r = -.50$; caregivers $n = 6$, $p = .046$, $r = .57$) and decreases in cortisol and cortisone for caregivers following singing ($n = 4$, $p = .068$, $r = -.65$). For PWD, there was significantly more HRV during the singing session compared to before and after and this was approaching significance for caregivers (during vs before $n = 7$, $p = .018$, $r = -.63$; during vs after $n = 7$, $p = .063$, $r = -.50$), as was the greater variability after compared to before ($n = 7$, $p = .063$, $r = -.50$). When comparing HRV across the sessions, none of the analyses were significant ($p > .015$), although the difference between HRV during and after the control condition was approaching significance, with a greater difference at the control condition ($n = 6$, $p = .028$, $r = -.64$). Effect sizes varied from trivial to large across the analyses, with the majority of large effects seen for increases in wellbeing and change in HRV at the singing session.
A summary of the Wilcoxon signed-rank test scores for the stress VAS, CWS and saliva hormones can be seen in Table 4 and for HRV in Table 5. Due to Bonferroni corrections being applied, the significance levels for the CWS analyses was $p < .008$ and for the HRV analyses was $p < .015$ whilst the significance level for the stress VAS and saliva analysis remained at $p < .05$. Pearson’s $r$ effect sizes were calculated according to Fields (2013) and classifications used were small ($r = .10$), medium ($r = .30$) and large ($r = .50$). In Table 4, analyses compared pre- and post- scores for PWD and caregivers for each condition (singing and control) and then compared the amount of change between the two conditions. In Table 5, analyses compared the amount of HRV in each time period (before, during and after) with one another and then also compared these differences across the two conditions.

**Qualitative findings**

The initial coding process identified 53 codes from seven interviews. The process of searching for themes and sub-themes by combining codes resulted in five themes being identified with 21 sub-themes (Table 6). The influence of the group on caregivers and PWD were categorised into separate themes to acknowledge the similarities and differences between these groups, whilst the remaining three themes related to aspects of the group experience that contributed to these influences. Five themes emerged which were not related to the research questions but contained interesting information such as experiences of caring for PWD. They have been included in Appendix O but not in further analysis in this report.
Theme 1 – Influence on PWD.

This theme highlights the observed differences as noticed by caregivers including positive changes in mood, behaviour and cognition. Alongside appearing more relaxed, caregivers also reported that they seemed more alert and active after the singing group and had improved language and organisation skills. The group allowed PWD to feel accepted for who they were and safe to be themselves. A further subtheme related to the length of time these changes were observed, particularly relevant in the context of the cognitive difficulties experienced by PWD. The effects noticed usually occurred during and after the group, sometimes for the rest of the day, it was seldom reported that these effects continued onto subsequent days.

Theme 2 – Influence on caregiver.

Some similarities were noted between the influence on the PWD and caregiver including positive mood changes. All caregivers reported enjoying the group and some felt more relaxed and optimistic afterwards. They also reported positive influences from observing the enjoyment of others, most often the person they care for. Two caregivers however, did not report any changes to their own mood. A couple also noted physical changes as a result of singing including changes to their voice and posture. Several described an impact on their feelings of identity from attending the group, allowing them to extend beyond their role into “more” than a caregiver. One caregiver reported feeling more tired following the group due to the air conditioning and concentration demands but still found the group a relaxing and rewarding experience.

Theme 3 – Singing in a group.

All caregivers reported that the activity of singing in a group was enjoyable for both themselves and the PWD. A couple commented on the positive impact of listening to music
in general but highlighted the particular influence of actively taking part. Two caregivers also commented on the positive experience of singing together with the person they care for and how this extended beyond the weekly sessions. Two caregivers highlighted the enjoyable experience of learning new songs, whilst one noted that more familiar songs were easier for the PWD to engage with.

**Theme 4 – Group dynamics.**

The theme of group dynamics related to processes or forces within the group which contributed to the influence of the group on participants. Six caregivers reported that socialising with others had a positive impact on the PWD, particularly their mood. Four also reported positive experiences of socialising in the group for themselves, particularly being in a group with other caregivers who had a shared understanding of this role. The welcoming, non-judgemental atmosphere of the group was also a group dynamic leading to positive influences on PWD and caregivers. This atmosphere was contributed to by the welcoming attitude and skills of the singing group staff.

**Theme 5 – Group mechanics.**

The theme of group mechanics encompassed the fixed aspects of the group which had an influence on group members as opposed to the interactional nature of dynamic sub-themes. Three caregivers reported the location of the choir as important, particularly the “posh” venue and geographical location in the centre of a large city. One caregiver explained that this made the choir feel like a “proper choir”. The other sub-theme that emerged under group mechanics was based on the timing of the group. Both the regularity of the group and the fact that the group was ongoing rather than time-limited were seen as positive influences.

</table>
Summary of qualitative analysis.

Caregivers reported multiple positive influences of participating in the singing group on themselves and the people they cared for. All of those interviewed highlighted the positive influence of the activity of singing. Doing so in a group was also reported to have positive influences and various other group dynamics and mechanics were reported, enhancing the experience. These included socialising with others for both PWD and their caregivers and the regular, ongoing nature of the group.

Discussion

The purpose of this exploratory study was to investigate the influence of a choral singing group on stress and wellbeing in PWD and caregivers using physiological and psychological measures. This study sought to expand previous research by adding novel psychophysiological measures alongside visual analogue scale measures of wellbeing (Johnson et al., 2017) and stress (Wewers & Lowe, 1990). In line with previous research (Camic et al., 2013), the overall results suggested that group singing had a positive effect on subjective wellbeing in PWD, and that physiological measurement has promise for detecting change in this population. A larger scale study is warranted to better understand relationships between physiological and psychological measures and qualitative reports during arts activities for this population.

Quantitative results

The first and third hypotheses were not supported (that salivary cortisol and subjective stress would decrease following singing and the decrease would be greater than the control session). Following the singing session, there were no significant differences in subjective stress or salivary cortisol and no significant differences compared to the control activity. The relatively stable subjective stress levels were similarly found in a previous study with this
population following music-based interventions (Camic et al., 2013). The findings may begin to provide evidence for the use of salivary cortisol as a physiological measure of stress, however further analysis using a pilot study is required to investigate the correlations between hormone and subjective stress levels. Caregivers had a significant decrease in cortisone, similar to previous findings in healthy populations (Fancourt et al., 2015).

On reflection, it could have been anticipated that there would not be a significant decrease in subjective and hormonal stress following the singing session. As the group was a weekly, ongoing activity that was reported to be enjoyable, it would not be expected that participants would be particularly stressed prior to the group. If some participants had experienced recent stressful life events, it may be likely that their scores would decrease more, due to higher stress levels beforehand, however this information was not collected. PWD reported a significant increase in stress following the control session, it is possible that this may have been due to disappointment that they were not singing as enjoyment of singing was noted in all interviews with caregivers and one participant was observed to begin singing at the start of the control condition.

Regarding the second hypothesis of this study, (wellbeing will increase following singing and the increase will be greater than the control condition) the findings partially support this. CWS subscale scores for happiness and optimism and the composite score significantly increased for PWD following the singing session. Although not significant following Bonferroni corrections, caregivers increased scores on the composite scale, happiness, wellness and optimism and PWD’s wellness scores were approaching significance. For both groups, the greater increases in happiness following singing compared to the control session were approaching significance. However, none of the increases were significantly greater, therefore the hypothesis is only partially supported. The increases in
CWS scores support findings from previous research into the effects of singing (Camic et al., 2013) on PWD and their caregivers.

The HRV data analysis showed trends for greater HRV during the singing session compared to before and after for PWD and caregivers, with significant differences for PWD. This may suggest that participants were engaged in the singing session and this had an impact on HRV. A recent pilot study looking at the relationship between HRV and the emotional states of happiness and sadness found a positive association between HRV variables and each emotional state (Shi et al., 2017). In this study, PWD in the singing condition were the only group-condition combination in which both significant effects of subjective happiness and significant increases in HRV were observed. There were also trends for more HRV during the control session compared to before and after for PWD but these were non-significant.

**Qualitative findings**

The thematic analysis of follow-up interviews with caregivers found five themes relating to the influence of the singing group on PWD and caregivers. Multiple positive influences were reported for both groups and the activity of singing seemed integral and was reported by one caregiver to be the “key” to the group’s positive influences. Other group dynamics and mechanics present in the group also contributed to the positive influences. Some subthemes that emerged in this study were similar to those reported in other studies including the enjoyment of singing, influence on mood and cognition, importance of staff characteristics, positive effects on caregivers of observing the enjoyment of those they care for and the extension of singing beyond the group when at home (Camic et al., 2013; Davidson & Almeida, 2014; Mittelman & Papayannopoulou; Osman et al., 2016; Unadkat et al., 2017). Caregivers reported that taking part in the singing group allowed PWD to express themselves and “be accepted for who they are”. Similar benefits were reported by Unadkat et
al. (2017) and this could be interpreted as allowing them to retain their personhood, as this involves self-expression, exercising choice and using their abilities (Kitwood, 1997). Another reported influence of the group was in allowing caregivers to retain an identity outside of that as a caregiver, related to Unadkat et al.’s subtheme of “release from caregiver burden”. The importance of reducing caregiver burden for the wellbeing of both PWD and caregivers was highlighted by Yaffe et al. (2002). The positive impact of belonging to a group and reducing social isolation for PWD was highlighted in this study by caregivers describing the influence of relationships with other group members and the ongoing nature of the group, this supports findings from previous studies (Unadkat et al., 2017; Eekelaar, Camic, & Springham, 2012).

**Connecting quantitative and qualitative findings**

Similarities were seen in the quantitative and qualitative findings in this study. Caregivers reported improvements in mood for both themselves and PWD from attending the singing group and this was substantiated by the increases in happiness reported on the CWS and increases in HRV. During interviewing, one caregiver reported feeling more optimistic after the group which was also shown in CWS increases for both PWD and caregivers. Both subjective stress and stress hormone levels remained relatively stable, providing preliminary evidence that this may be a feasible way of measuring stress in this population.

This study focused on “in the moment” effects of taking part in the singing group on PWD. This was related to the “length of influence” subtheme in the thematic analysis, with most caregivers reporting that effects of the group were relatively short-term. This was anticipated in the context of PWD’s cognitive difficulties but some caregivers reported a longer-term influence of being part of the group (e.g. looking forward to sessions and singing at home). Although the length of influence on caregivers was not discussed in this study, a
previous RCT found that group singing had positive effects on long-term wellbeing with this population (Särkämö et al., 2013).

**Limitations**

As this was an exploratory study, it is not possible to draw definitive conclusions about the effects of group singing. Therefore, any conclusions regarding the effects of group singing based on these results should be made with caution. This was particularly relevant for the stress hormone analyses as there were difficulties with saliva collection and they were based on very small participant numbers. In addition, only a small proportion of results were statistically significant and results approaching significance have also been highlighted in this project. These have been included due to the possibility of Type 2 errors (incorrectly accepting the null hypothesis) due to small sample sizes and the application of strict Bonferroni corrections, however their inclusion increases the risk of Type 1 errors (incorrect rejection of the null hypothesis). The issue of whether to comment on results approaching significance is a contentious one as a significant difference has not been found, therefore it cannot be said that there has been an effect on the dependent variable. Due to the exploratory nature of this study and restrictive aspects of the analysis (Bonferroni and small sample size), the approaching significance results have been included in this project to guide further research, however it is important to note that they cannot be said to indicate change.

Demographic information indicated that the balance of male and female PWD was roughly similar but caregivers were predominantly female. The majority had a diagnosis of Alzheimer’s disease which may bring into question the applicability of results to those with other dementia diagnoses; however, this is reflective of the prevalence seen in the wider population and diagnostic information is not often available in research investigating the effects of the arts on people with dementia. The subjective VAS data may have been subject
to demand characteristics, particularly with caregivers, who may have predicted the aims of the study. The possibility of the impact of this was reduced by not having pre-scores available at the time of completing post-measures.

There were also limitations associated with saliva collection. As this was a community-based project, the researchers did not have the opportunity to control participants’ activities prior to attending the group. Although the researchers were able to ensure that participants did not have a drink in the twenty minutes before giving saliva samples, they were not able to control for participants eating in the hour prior to attending, which can affect hormone levels. The measures completed at the control session may have been affected by the change in location and the high external temperature that day (30°C). Although participants were given the opportunity to familiarise themselves with the art gallery at a previous session, this may have contributed to the more varying data seen following art-viewing.

The interviews were only conducted with caregivers to minimise the disruption to PWD’s routine (as it was a pre-existing group) and due to possible difficulties recalling their experiences which could have caused distress. During the process of obtaining consent, multiple caregivers said that it would not have been helpful to interview the person they cared for as they would not recall having attended the group a day or so later. Therefore, whilst the interviews gave an account of caregiver experiences, it was an indirect exploration of how PWD experienced the singing group and its perceived influence. The pre- and post-measures did indicate positive influences of the group but more in-depth exploration of their own experiences was not obtained.

As the cortisol and cortisone measures did not always appear to correlate with the subjective stress measure (e.g. PWD reported an increase in stress and had non-significant
CHOURAL SINGING, DEMENTIA, STRESS AND WELLBEING

decreases in cortisol and cortisone levels following the control condition), it is possible that
different phenomena were being measured and it is important for future studies to investigate
this further.

Choosing an appropriate control condition in this study was a particularly challenge as
there was no existing standard control condition for community singing groups with PWD.
Both within-subject and between-subject control groups were considered, however due to
time constraints it was not possible to recruit a between-subjects group (who would also need
to be matched to the singing participants). To provide a within-subjects comparison, it was
decided that the control condition should have similar characteristics to the singing session,
for example in a prestigious building, in a group setting, with similar levels of movement and
led by an experienced facilitator. Various within-subject control conditions were considered
including sitting in a waiting-room, looking at postcards of art and the art-viewing session
chosen. This was chosen in consultation with the choral group organisers and service users
who were part of an organisation related to the project, as the most ethical option to engage
PWD rather than inviting them to take part in an activity which would likely not be
stimulating for them. There were, however, limitations to the choice of this control condition
including that differences would be less likely to be observed when compared to the singing
session because it was more engaging than a waiting-room control group.

Clinical implications

As a result of this exploratory study and findings from previous studies (e.g. Camic et
al., 2013; Unadkat et al., 2017), it is tentatively suggested that ongoing choral singing groups
are useful community-based activities with this population and may be considered as part of
social prescribing schemes being encouraged by NHS England (Chatterjee, Thomson,
Lockyer, & Camic, 2017). Clinical psychologists could recommend singing groups to PWD
and their caregivers to support wellbeing for early to mid-stage dementias. They could also provide consultation to colleagues in mental health and social services on the effects of group singing with these populations, increasing awareness and signposting to relevant groups. Increasing wellbeing for both PWD and caregivers may enhance the possibility of remaining living at home rather than moving into residential care and allow people to maintain more of their personhood (Kitwood, 1997; Yaffe et al., 2002). Furthermore, there may also be implications for public health policy supporting community-based arts and health programmes (APPG, 2017). Reducing caregiver burden may also have positive implications for health and social care services due to the links between these factors and physical and mental health (Pinquart & Sörensen, 2003). Therefore, it may be cost effective to fund similar singing groups associated with improvements in wellbeing (Camic et al., 2013; Unadkat et al., 2017). It is important to note that these implications are based on both the findings from this study and findings from other studies (e.g. Camic et al., 2013; Unadkat et al., 2017) and that only a small proportion of results in the current study were significant, with a larger number “approaching significance”, the inclusion of which is a contentious issue. Caregivers also made recommendations which could be incorporated into the existing singing group, which have been passed on to the organisers.

**Research implications**

The results from this study indicate that further research is warranted to better understand the interaction of physiological and psychological aspects of choral singing for both PWD and caregivers. Future research should consider the methodological difficulties encountered in this exploratory study. It would be helpful to allow additional time for data collection and to use an alternative form of saliva sample collection (the passive drool technique), increasing the likelihood that more saliva is collected for a viable analysis. Wearable sensors (e.g. Empatica® wristbands) are a non-intrusive and easy to administer
method of physiological data collection, that can collect multiple continuous measurements including heart rate, skin conductance and movement. A larger scale, between-subjects pilot study is suggested to further investigate correlations between physiological and psychological measures of stress and wellbeing. It would also be expedient to undertake a longitudinal study where measurements are collected over multiple intervention and control sessions. Further qualitative research could include interviews with PWD immediately after a singing group to gain their opinions on the influence of the group. Although a specifically relational measure was not used in this study, it is possible that being part of a dyadic singing group could have an impact on the relationship between the PWD and caregiver. The measures used in this study related to the dyadic nature of the group in that any impact of the intervention on the PWD may in turn impact the wellbeing and stress levels of the caregiver and vice versa. This could be due to observing the other person enjoying themselves (as reported in the interviews with caregivers) and through a sense of achievement and mastery. Future research could include measures focusing more specifically on the dyadic relationship or correlational analyses looking at any relationships between change on individual measures of wellbeing and stress between each member of the dyad.

**Conclusion**

The present exploratory study cautiously supports that there are positive interrelationships between psychological measures of wellbeing and physiological measures of heart rate variability during a choral singing group for people with a dementia. There were also similarities between outcomes on psychological measures of stress and saliva hormone data. This is the first study of its kind to combine these physiological measures with this population. The ease of obtaining heart rate data was a particular contribution and can be explored in future research. A larger scale study of choral singing is warranted to better understand these interrelationships. Further research is needed to address the methodological
CHORAL SINGING, DEMENTIA, STRESS AND WELLBEING

challenges encountered in this study, most notably the difficulties obtaining sufficient amounts of saliva for analysis, should this method be used in the future. Studies with larger sample sizes, a between-subjects design and data collection over multiple sessions would also allow more definitive conclusions to be drawn. Notwithstanding, there are implications for clinicians working with this population including improving awareness and access to these activities as well as public health policy implications that support community-based arts and health programmes (APPG, 2017) through social prescribing schemes.

Appendix D – Consent form

Consent Form (page 1 of 2)

Participant ID: ________________

Title of Project: Impact of choral singing

Name of Researchers: Philippa Bourne and Professor Paul Camic

Please initial each box if you agree

1. I confirm that I have read and understand the information sheet for the above study. I have had the opportunity to consider the information, ask questions and have had these answered satisfactorily.

2. I understand that my participation is voluntary and that I am free to withdraw at any time without giving any reason.

3. I will complete brief questionnaires and give a sample of my saliva before and after one singing group and one activity at the [Venue 2]. I give my permission for both of these to be done. I also agree to wear a wristband to measure some of my body’s activities.

4. I agree to be contacted to take part in a brief telephone follow up interview (approx. 15 minutes) to be asked questions about the singing group and for anonymous quotes from the interviews to be used in published reports of the study findings.

6. I understand that anonymous data from this project will be available to Canterbury Christ Church University and University College London researchers and that results from this project will be submitted as part of a doctoral thesis and for journal publication and that information from the study may be used in future research projects.

7. I agree to take part in the above study.

Appendix E – Participant information sheet

**Information about the Choral Singing Research Project**

Hello. Our names are Philippa Bourne and Professor Paul Camic and we are researchers at Canterbury Christ Church University; Philippa is completing her doctoral degree in clinical psychology and Paul is the Research Director. We would like to invite you to take part in a research project about how singing may help people with memory problems and their family members or friends.

Before you decide, it is important that you understand why the research is being done and what it would involve for you. You are welcome to tell others about the study if you wish.

**Part 1** of this sheet tells you the purpose of this study and what will happen if you take part.

**Part 2** gives you more detailed information about how the study will be conducted.

**Part 1**

**What is the purpose of the study?**

The purpose of the study is to obtain information from you on how a choral singing group might help people with memory problems and their family members or friends.

**Why have I been invited?**

You have been invited to take part in the study because you are attending the choral singing group at [Venue 1].

**Do I have to take part?**

No, you do not have to take part. It is entirely up to you to decide to join the research. If you agree to take part, we will then ask you to sign a consent form. You can withdraw at any time and you do not have to give a reason. This would not affect your ability to take part in the singing group or any other programme at [Venue 1].

**What will I have to do?**

Attend the singing groups as you have planned.

1. At your singing session on [Date 1] we will give you a brief questionnaire to complete before and after the session.

2. We will also take a sample of your saliva before and after the session. We will ask you to hold a small piece of hygienic sponge in your mouth for just 60 seconds and chew it. We will then take the sponge and put it in a bottle.

3. You may also be asked to wear a wristband that looks like a watch to measure some of your body’s activities during both sessions.
4. There will also be another activity based at the [Venue 2] on [Date 2] and [Date 3] you will be invited to.

5. On [Date 3] we will ask you to complete the brief questionnaire and give a saliva sample at the beginning and end of this session, just as you will have done on [Date 1].

Please do not have any food in the hour before the session or any beverages for 20 minutes before as this may affect the results of the study. Water will be provided during the singing session and refreshments will be provided after.

**What are the possible disadvantages and risks of taking part?**

When holding the sponge in your mouth it is important not to swallow it as it could be a choking hazard. There will be a member of the research team available to guide you through this process.

**What are the possible benefits of taking part?**

The results of this study may be used to help find funding for similar programmes in the future and to better understand the impact of choral singing.

**Will my taking part in this study be kept confidential?**

Your confidentiality will be safeguarded during and after the study. You will be given a participant number which will be on all questionnaires and the sample of your saliva. They will be kept in a safe place during and after the study.

**Who has approved the study?**

All research involving people, including this study, is looked at by an independent group of people called a Research Ethics Committee, to protect your interests. This study has been reviewed and given approval by Canterbury Christ Church University Research Ethics Committee on 22 February 2017.

**Who is organising and funding the research?**

Canterbury Christ Church University and the Created Out of Mind Hub at the Wellcome Collection are funding the research. [Partner organisation] and [Venue 1] are helping organise the singing groups and are partners in this research.

**Part 2**

**What will happen if I don't want to carry on with the study?**

If you change your mind about participating in the research, but still want to come to the singing groups, that is absolutely fine to do. You can simply let us know at the beginning of the group. You do not have to give a reason.

**What if there is a problem?**

If there is a problem during the session, you can ask one of the facilitators to help you or to give you more information.
Concerns and Complaints

If you have any concerns about the research, please contact the lead researcher: Philippa Bourne, Salomons Centre for Applied Psychology, Canterbury Christ Church University, p.bourne366@canterbury.ac.uk. You can also leave a message on the 24-hour voicemail 01892 507673 with your name and number, please say you are leaving the message for Philippa and she will get back to you.

If you would like to make a complaint about any aspect of the research please contact: Professor Margie Callanan, Chair, university ethics panel at Salomons Centre for Applied Psychology, Canterbury Christ Church University at margie.callanan@canterbury.ac.uk or telephone 03330 117 094.

What will happen to the results of the research study?

We will send you an information sheet at the end of the study letting you know what we have learnt from it. Please inform the researchers if you do not wish to receive this. It is hoped that the results of the study will be published in a journal. We may use some anonymous quotes from interviews, but if your quotes are used, we will ensure that it will not be possible to identify you from the quotes. An anonymous write-up of the results will be published on the Canterbury Christ Church University website. The data will also be anonymously shared with University College London researchers.

Further information and contact details

If you would like to speak to us and find out more about the study or have questions, you can leave a message for Philippa on a 24-hour voicemail phone line at 01892 507673. If she is not available, please leave a contact number so that she can get back to you. You can also email her at p.bourne366@canterbury.ac.uk.

Thank you

Appendix G - Canterbury Wellbeing Scales and stress VAS scale

This has been removed from the electronic copy
Appendix H - Further details of Empatica® procedure and data analysis

Initial HRV data analysis was completed by Rachel Hughes (University College London). The information below is directly quoted from her MSc thesis (Hughes, 2016/2017).

“Background: This study used the Empatica E4 wristband which contains a photoplethysmography (PPG) sensor which is able to calculate HR, HRV and blood volume pulse, an accelerometer and an EDA sensor to measure galvanic skin response (or skin conductance) (Empatica, 2017). Interest lies within HR monitoring and how PPG sensors works. The wristband contains a light emitting diode (LED) which is shone directly onto the skin and determines HR using the theory that arterial blood flow is inversely proportionate to the amount of reflected light (Spierer et al., 2015, Stahl et al., 2016). This means that if more light is reflected the arteries are dilated resulting in lower blood pressure and HR (Siddiqui, 2011), with the opposite being true for less light reflection”.

Procedure

“Empaticas were turned on, placed on a table and synchronised by filming the table being banged twice, with the Unix time stamp visible. The table bang produced a simultaneous event which caused rapid increases in acceleration in multiple directions, visible across all devices.

The Unix time stamp was noted when each session started and at various points throughout”.

Data Analysis

“This used PPG sensors to generate the blood volume pulse. Peaks were then detected from the PPG and the lengths of the intervals between each peak, or beat, was generated. This found the inter-beat interval. From this, instantaneous HR could be estimated. This process
was computer generated and resulted in a HR measurement each second (Empatica Support, 2016).

Data from all Empatica wristbands were uploaded onto Empatica Connect (https://www.empatica.com/connect/login.php). Individual excel files were downloaded. The files were sorted into those from the singing session and those from the art viewing session.

To synchronise the data, the first peak in the accelerometer data caused by the table banging was identified and a record was made of what time this occurred on the device. Any HR measures before the recorded time were deleted. This ensured that all Empatica E4 wristbands had the same start time.

A typed transcript was made of each session to identify what happened at major time points. This was done by listening to the audio recordings of each session and making a note of the major events. Using the audio time log, the Unix time stamp for each second was able to be produced”.

Statistics

“Mean HR variance was calculated for each participant. The mean and standard deviation (SD) of patients and controls was calculated for each subdivision. Data was then baselined for each participant individually to calculate HR (variance) change by subtracting their mean HR (variance) before from their mean HR (variance) during and after each session”.

Appendix I - Interview schedule

Hi, my name is [interviewer name]. I am one of the researchers doing the study at the singing group at [Venue 1]. Is now a good time to have a short conversation about the singing group? It should take no more than 15 minutes. Great! Just to let you know that I will be recording our call so that I don’t miss any of the information but the recording will be destroyed after I have typed it up.

First I would like to ask you about your experiences of the group…

1. Do you enjoy coming to the singing group at [Venue 1]?
   1a. Can you describe what it is about the group that you enjoy?

2. Do you notice any differences in yourself whilst you are at the group or afterwards? 
   *If mood is not covered go to question 3*

3. Does it have any impact on your mood either positively or negatively?
   3a. Why do you think it has an impact?

Thank you, now I would like to ask you your opinion of (insert name)’s experience of the group…

4. Do you think (insert name) enjoys coming to the singing group at [Venue 1]?
   4a. Can you tell me in a few words why you think (name) enjoys coming to the singing group?

5. Do you notice any differences in (insert name) whilst (s)he is at the group or afterwards?
6. Why do you think it is the singing group which causes these differences?
   (Is there anything in particular about the singing sessions which you feel may have this effect?/ do they seem different or behave differently at [Venue 1] compared to other times in the week)
   *If mood is not covered go to question 6*

6. Does it seem to have any impact on (insert name)’s mood either positively or negatively?
   And in what way?
7. Anything else about your experiences or PWD’s experiences that are important for me to know?

Thank you

Appendix Q – Submission guidelines for intended journals

Section A: Psychogeriatrics

Edited By: Toshihisa Tanaka

Impact Factor: 1.693

ISI Journal Citation Reports © Ranking: 2016: 37/49 (Geriatrics & Gerontology); 94/142 (Psychiatry)

Online ISSN: 1479-8301

Author Guidelines

1. MANUSCRIPT SUBMISSION

Please read the complete Author Guidelines carefully, including the section on copyright, before submitting your manuscript. Please note page charges apply if articles are longer than the specified page lengths.

Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at: http://mc.manuscriptcentral.com/psy.

For assistance, please contact the Psychogeriatrics Editorial Office at the address below:

Psychogeriatrics Editorial Office
c/o John Wiley & Sons Australia
155 Cremorne Street Richmond, VIC 3121, Australia
E-mail: psyg.eo@wiley.com
Tel: 03 3830 1263 (Residents in Japan), +61 3 9274 3129 (Residents outside Japan)
Fax: +61 3 9274 3101

2. EDITORIAL AND CONTENT CONSIDERATIONS

Aims and scope

Psychogeriatrics is an international journal sponsored by the Japanese Psychogeriatric Society that publishes peer-reviewed original papers dealing with all aspects of psychogeriatrics and related fields. The Journal encourages articles with gerontopsychiatric, neurobiological, genetic, diagnostic, sociopsychiatric, psychological, or psychotherapeutic content, as well as content related to health policy. Themes can be illuminated through basic science, clinical (human and animal) studies, case studies, epidemiological research, and humanistic research.

Editorial review and acceptance

Manuscripts are accepted regardless of whether the author is a member of the Japanese Psychogeriatric Society.
Submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. The acceptance criteria for all papers are the quality and originality of the research and its significance to our readership. Except where otherwise stated, manuscripts are double-blind peer reviewed by two anonymous reviewers and the editor.

Once contributions have been judged as acceptable for publication on the basis of content, the editor and the publisher reserve the right to modify manuscripts to eliminate ambiguity and repetition and to improve communication between author and reader. Final acceptance or rejection rests with the editorial board, which reserves the right to refuse any material for publication.

3. MANUSCRIPT CATEGORIES AND REQUIREMENTS

(1) Original Article
Word limit: approximately 4000 words
Abstract: 300 words or fewer, structured

(2) Review Article
Word limit: approximately 6500 words
Abstract: 300 words or fewer, unstructured

(3) Case Report
Word limit: approximately 1500 words
Abstract: 300 words or fewer, unstructured
References: up to 5
Figures/tables: up to 5

(4) Psychogeriatric Note
Word limit: approximately 800 words
Abstract: none
References: up to 7
Figures/tables: up to 1
Psychogeriatric Notes are concise reports, in particular, focusing on techniques used to overcome problems as well as on skills or problems that may be of great interest. It should not include a detailed report or discussion. The text is unstructured (i.e. no subheadings).

(5) Letter to the Editor
Word limit: approximately 500 words
Abstract: none
References: up to 5
4. ETHICAL CONSIDERATIONS

Psychogeriatrics is committed to integrity in scientific research and recognizes the importance of maintaining the highest ethical standards.

Committee on Publication Ethics

The journal is a member of, and subscribes to, the principles of the Committee on Publication Ethics (COPE) (http://publicationethics.org/).

Authorship and acknowledgements

The journal adheres to the definition of authorship established by the International Committee of Medical Journal Editors (ICMJE). The ICMJE recommends that authorship be based on the following four criteria: (i) substantial contributions to the conception or design of the work or to the acquisition, analysis, or interpretation of data for the work; (ii) drafting the work or revising it critically for important intellectual content; (iii) final approval of the version to be published; and (iv) agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved. Contributors who do not qualify as authors should be mentioned under ‘Acknowledgments’.

Declaration of Helsinki

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil, 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. The text should also clearly state that all persons gave informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted.

Use of animals in research

Reports of animal experiments must state that the ‘Revised guide for the care and use of laboratory animals’ (NIH Publication Vol 25, No. 28 revised 1996; http://grants.nih.gov/grants/guide/notice-files/not96-208.html) were followed and, where applicable, indicate that specific national laws (e.g. the current version of the German Law on the Protection of Animals) were followed.

Conflict of interest

Authors must declare any financial support or relationships that may pose conflict of interest. At the time of submission, authors must disclose any financial arrangements with a company whose product figures prominently in the submitted manuscript or with a company making a competing product. Such information will be requested on the ScholarOne submission site and will be included in a Disclosure statement between the Acknowledgments and References sections of their manuscript.

Data Sharing and Data Accessibility
The journal encourages authors to share the data and other artefacts supporting the results in the paper by archiving it in an appropriate public repository. Authors should include a data accessibility statement, including a link to the repository they have used, in order that this statement can be published alongside their paper.

5. PREPARATION OF THE MANUSCRIPT

Pre-acceptance English-language editing

Authors for whom English is a foreign language may choose to have their manuscript professionally edited before submission. Visit the Wiley Editing Services site to learn about the options offered. All services are paid for and arranged by the author. Please note using Wiley Editing Services does not guarantee that a paper will be accepted by the Journal.

Optimizing your article for search engines

Many students and researchers looking for information online will use search engines such as Google or Yahoo. By optimizing your article for search engines, you will increase the chance of someone finding it. In turn, this will make it more likely to be viewed and/or cited in another work. We have compiled these guidelines to enable you to maximize the Web-friendliness of the most public part of your article.

Manuscript format and style

Manuscripts should follow the ICMJE’s Recommendation for the Conduct, Reporting, Editing and Publication of Scholarly Work in Medical Journals (formerly known as the ‘Uniform Requirements for Manuscripts’).

Journal style

Spelling. Psychogeriatrics publishes in British English. For word usage and word division, please refer to the latest edition of the Oxford Concise English Dictionary.

Abbreviations. In general, terms should not be abbreviated unless they are used at least three times after the abbreviation is introduced and the abbreviation is helpful to the reader. Initially, use the word in full and present the abbreviation in parentheses after the term. Thereafter, use the abbreviation only.

Quotations. Use single quotation marks for citations (‘’).

Asterisks. Please note that asterisks must not be used (**).

Units of measurement. All measurements must be given in SI or SI-derived units. Visit the Bureau International des Poids et Mesures (BIPM) website at http://www.bipm.fr for more information about SI units.

Trade names. Chemical substances should be referred to by the generic name only. Trade names should not be used. Drugs should be referred to by their generic names. If proprietary drugs have been used in the study, refer to these by their generic name, and in parentheses, mention the proprietary name and the manufacturer’s name and location (city, state, country).
Genetic nomenclature. Standard genetic nomenclature should be used. For further information, including relevant websites, authors should refer to the genetic nomenclature guide in Trends in Genetics (Elsevier Science 1998).

Nucleotide sequence data. Nucleotide sequence data can be submitted in electronic form to any of the three major collaborative databases: DDBJ, EMBL, or GenBank. It is only necessary to submit to one database, as data are exchanged between DDBJ, EMBL, and GenBank on a daily basis. The suggested wording for referring to accession-number information is: ‘These sequence data have been submitted to the DDBJ/EMBL/GenBank databases under accession number U12345’. Addresses are as follows:

• DNA Data Bank of Japan (DDBJ) http://www.ddbj.nig.ac.jp
• EMBL Nucleotide Sequence Submissions http://www.ebi.ac.uk

Parts of the manuscript

Manuscripts should be presented in the following order: (i) title page; (ii) abstract and key words; (iii) main text; (iv) acknowledgements; (v) disclosure statement; (vi) references; (vii) figure legends; (viii) tables (each table complete with title and footnotes); and (ix) figures. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Title page

The title should be informative and contain the major key words. Do not use abbreviations in the title. A short running title (less than 40 characters including spaces) should also be provided.

The title page must contain both a descriptive and concise title of the paper; names and affiliations (including institution location) of all authors; information for the contact author including qualifications (e.g. MD, PhD), full mailing address, email address, and a contact telephone number. The present affiliation of any author, if different from that where the work was carried out, should be supplied in a footnote.

A statement should be included to indicate to which of the six available fields of the journal - (Clinical and Basic) Pharmacology and Neurochemistry, Dementia Care and Epidemiology, BPSD and Non-pharmacological Therapy, Neuropsychology, Functional Brain Imaging and Physiology, and Others - the manuscript is being submitted. “Others” should be chosen only when the other fields are not suitable.

Abstract and key words

All manuscripts, except Case Reports, must include a brief but informative abstract that states the purpose, basic procedures, main findings, and principal conclusions of the study in 300 words or fewer. For Original Articles, the abstract should be divided into four sections with the following headings: Background, Methods, Results, and Conclusions. The abstract should not contain references. Abbreviations may be included if they are used more than three times within the abstract.
Key words (between three and six) for the purposes of indexing should be supplied below the abstract in alphabetical order. They should be taken from those recommended by the US National Library of Medicine’s Medical Subject Headings (MeSH) browser list: http://www.nlm.nih.gov/mesh/meshhome.html

Introduction

This section should include sufficient background information to set the work in context. The aims of the manuscript should be clearly stated.

Methods

This should be concise but provide sufficient detail to allow the work to be repeated by others. The source of materials should be given in detail, where possible. Ethical considerations should be detailed.

Results

Results should be presented in a logical sequence in the text, tables, and figures. Repetitive presentation of the same data in different forms should be avoided.

Discussion

This should consider the results in relation to any hypotheses advanced in the introduction and place the study in the context of other work.

Acknowledgments

This should include sources of support, including federal and industry support. Medical writers, proofreaders, and editors should not be listed as authors but may be acknowledged in the Acknowledgment section.

Disclosure statement

Authors should declare any financial support or relationship that may pose conflicts of interest as a Disclosure statement between the Acknowledgments and References sections of their manuscript. The absence of any interest to disclose must also be stated as, ‘The authors have no potential conflicts of interest to disclose’.

References

References follow Vancouver style - that is, they are numbered sequentially as they occur in the text and ordered numerically in the reference list.

• All citations mentioned in the text, tables, or figures must be listed in the reference list.
• If cited in tables or figure legends, number according to the first identification of the table or figure in the text.
• In the reference list, cite the names of all authors when there are six or fewer; when there are seven or more, list the first three followed by et al.
• Do not use ibid. or op cit.
• Reference to unpublished data and personal communications should not appear in the list but should be cited in the text only (e.g. Smith A, 2000, unpublished data).

• Names of journals should be abbreviated according to the Serial Sources for the Biosis Data Base, which is available in most libraries or from http://www.biosis.org

• Authors are responsible for the accuracy of the references.

• Authors can read more about the Vancouver reference style here.

Below are sample references formatted according to Vancouver style:

Journal article

Online article not yet published in an issue
An online article that has not yet been published in an issue—and therefore has no volume, issue or page numbers—can be cited by its Digital Object Identifier (DOI). The DOI will remain valid and allow an article to be tracked even after its allocation to an issue. Shibata N and Arai H. Alzheimer’s disease and mortality in Japan. Psychogeriatrics doi:10.1111/j.1479-8301.2009.00273.x

Book

Chapter in a book

Electronic material
Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive—the table, legend, and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order), and *, **, *** should be reserved for defining P-values. Statistical measures such as SD or SEM should be identified in the column or row headings. If you use a table editor function, ensure that each data point is contained within a unique cell—do not use carriage returns within cells.

Figure legends

Include figure legends on a separate page. Legends should be concise but comprehensive—the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement. (If figures have been reproduced from another source, provide a letter stating exclusive licence authorization.)

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals and cited in consecutive order in the text. Figures should be sized to fit within the column (84 mm) or the text width (175 mm). Magnifications should be indicated using a scale bar on the illustration. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of electronic figures for publication

Although low-quality images are adequate for review purposes, print publication requires high-quality images to prevent the final product being blurred or fuzzy. Submit EPS (line art) or TIFF (halftone/photographs) files only. MS PowerPoint and Word graphics are unsuitable for printed pictures. Do not use pixel-oriented programmes. Scans (TIFF only) should have a resolution of 300 dpi (halftone) or 600–1200 dpi (line drawings) in relation to the reproduction size (see below). EPS files should be saved with fonts embedded (and with a TIFF preview if possible).

For scanned images, the scanning resolution (at final image size) should be as follows to ensure good reproduction: line art, >600 dpi; half-tones (including gel photographs) >300 dpi; and figures containing both halftone and line images, >600 dpi.

Further information on Wiley’s guidelines for figures (‘Electronic artwork guidelines’) can be obtained from: http://authorservices.wiley.com/bauthor/illustration.asp

Supporting information

Supporting information is not essential to the article but provides greater depth and background. It may include tables, figures, videos, and/or datasets. This material can be submitted with your manuscript, and will appear online, without editing or typesetting.
Guidelines on how to prepare this material and which formats and file sizes are acceptable can be found at: http://authorservices.wiley.com/bauthor/suppmat.asp

Please note that the provision of supporting information is not encouraged as a general rule. It will be assessed critically by reviewers and editors, and will only be accepted if it is essential.

6. SUBMISSION REQUIREMENTS

The main text file should be prepared using Microsoft Word in a double-spaced A4 document. The top, bottom, and side margins should be 30 mm each. All pages should be numbered consecutively in the top right corner, beginning with the first page of the main text file. Each figure should be supplied as a separate file, with the figure number incorporated in the file name. Files saved as .ppt are not acceptable at any stage. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 dpi) saved as .eps or .tif files should be uploaded. Digital images supplied only as low-resolution files cannot be used.

Associate your ScholarOne account with your ORCID iD

ORCID iD is a unique and persistent identifier that distinguishes you from every other researcher and connects you and your research activities. We encourage you to register today for your ORCID iD and then associate it with your ScholarOne account. Click here to find out how.

7. COPYRIGHT, LICENSING, AND ONLINE OPEN

If your paper is accepted, the author identified as the formal corresponding author for the paper will receive an email prompting them to login into Author Services; where via the Wiley Author Licensing Service (WALS) they will be able to complete the license agreement on behalf of all authors on the paper.

For authors signing the copyright transfer agreement

If the OnlineOpen option is not selected the corresponding author will be presented with the copyright transfer agreement (CTA) to sign. The terms and conditions of the CTA can be previewed in the samples associated with the Copyright FAQs below:

CTA Terms and Conditions http://exchanges.wiley.com/authors/faqs---copyright-_301.html

For authors choosing OnlineOpen

If the OnlineOpen option is selected the corresponding author will have a choice of the following Creative Commons License Open Access Agreements (OAA):

Creative Commons Attribution License OAA

Creative Commons Attribution Non-Commercial License OAA

Creative Commons Attribution Non-Commercial -NoDerivs License OAA

To preview the terms and conditions of these open access agreements please visit the Copyright FAQs hosted on Wiley Author Services http://exchanges.wiley.com/authors/faqs--
If you select the OnlineOpen option and your research is funded by certain funders [e.g. The Wellcome Trust and members of the Research Councils UK (RCUK) or the Austrian Science Fund (FWF)] you will be given the opportunity to publish your article under a CC-BY license supporting you in complying with your Funder requirements.

For more information on this policy and the Journal’s compliant self-archiving policy please visit: http://www.wiley.com/go/funderstatement.

8. PUBLICATION PROCESS AFTER ACCEPTANCE

Wiley’s Author Services: tracking your paper’s progress

Accepted papers will be passed to Wiley’s production team for publication. The author identified as the corresponding author for the paper will receive an email prompting him or her to login into Wiley’s Author Services. Author Services enables authors to track their article through the production process, to publication online and in print. Authors can check the status of their articles online and choose to receive automated emails at key stages of production. The corresponding author will receive a unique link that enables him or her to register and have the article automatically added to the system. Please ensure that a complete email address is provided when submitting the manuscript. Visit http://authorservices.wiley.com/checklist.asp for more details on online production tracking and for a wealth of resources including FAQs and tips on article preparation and submission.

Proofs

Once the paper has been typeset the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; responsibility for detecting errors lies with the author.

Early View

The journal offers rapid speed to publication via Wiley’s Early View service. Early View articles are complete full-text articles published online in advance of their publication in a printed issue. Early View articles are complete and final. They have been fully reviewed, revised and edited for publication, and the authors' final corrections have been incorporated. Because they are in final form, no changes can be made after online publication. Early View articles are given a Digital Object Identifier (DOI), which allows the article to be cited and tracked before allocation to an issue. After print publication, the DOI remains valid and can continue to be used to cite and access the article. More information about DOIs can be found at http://www.doi.org/faq.html.

9. POST PUBLICATION

Article PDF for authors

A PDF of the article will be made available to the corresponding author via Author Services.

Printed Offprints
Printed offprints may be ordered online for a fee. Please click on the following link and fill in the necessary details and ensure that you type information in all of the required fields: http://offprint.cosprinters.com/cos. If you have queries about offprints please e-mail: offprint@cosprinters.com.

Author Marketing Toolkit

The Wiley Author Marketing Toolkit provides authors with support on how to use social media, publicity, conferences, multimedia, email and the web to promote their article.

Psychogeriatrics has adopted CrossCheck plagiarism software. The journal to which you are submitting your manuscript employs a plagiarism detection system.

Section B: Dementia: The International Journal of Social Research and Practice

Dementia

2016 Impact Factor: 1.768
2016 Ranking: 14/32 in Gerontology

Source: 2016 Journal Citation Reports® (Clarivate Analytics, 2017); Indexed in PubMed: MEDLINE

The International Journal of Social Research and Practice

Description

Dementia: The International Journal of Social Research and Practice has proved an exciting step forward for the field of dementia care generally, and social research specifically. Dementia acts as a major forum for social research of direct relevance to improving the quality of life and quality of care for people with dementia and their families.

The Journal has proved an exciting step forward for the field of dementia care generally, and social research specifically. It acts as a major forum for social research of direct relevance to improving the quality of life and quality of care for people with dementia and their families.

"Dementia will be of interest to all clinical disciplines involved in dementia research and the care of individuals with dementia and will be a valuable addition to many libraries and personal collections. It undoubtedly fills a gap among the mass of journals and will make a significant contribution to the
effective dissemination of research and the development of high-quality clinical practice." Times Higher Education Supplement

"There is now increasing attention being given to psycho-social aspects of the dementias, with a better balance with biomedical factors being apparent. The journal Dementia has played a key role in developing good quality research in this domain, across a variety of disciplines. It has already contributed to developing and disseminating better practice and quality of care, as we have come to understand better the impact of social and psychological factors on people with dementia and their supporters." Bob Woods, Bangor University

"The field of social research and practice development in dementia care is growing rapidly. There is a compelling need for the key players - people living with dementia, their families and the range of professions supporting them - to work together towards realising the full potential of people living with dementia. The Journal provides just such a forum." Murna Downs, University of Bradford, UK

"Dementia research has come of age and recognizes the value of studying psychosocial aspects related to this disease. Dementia serves an important role in the dissemination of studies on how to improve quality of care and thereby quality of life in people with dementia and their informal caregivers. It also offers a forum for studies on care staff, which is increasingly important since many countries struggle with a lack of well-educated staff. Dementia helps academics, educators, students, professionals working in dementia care and policy makers in acquiring knowledge and valuation of psychosocial aspects related to dementia. It is a new but well-regarded journal, with an international perspective and a willingness to publish cross-boundary and innovative research which makes it essential reading." Prof. M. Vernooij-Dassen, Radboud University Medical Center Nijmegen, the Netherlands.

This journal is a member of the Committee on Publication Ethics (COPE).

The aim of the journal is to publish original research, or original scholarship contributions, to the existing literature on social research and dementia. The journal will consider all relevant designs, methods and methodologies that meet this aim. The journal will also consider narrative-based and/or other forms of literature review that seek to answer social research questions in dementia studies; however, such reviews need to have a systematic approach to literature collation and reporting. All original research published in the journal must comply with ethical approval processes.

Dementia is hosted on SAGE track; a web based online submission and peer review system powered by ScholarOneTM Manuscripts. Please visit http://mc.manuscriptcentral.com/dementia to log in and submit your article online.

All original papers must be submitted to the journal via the online system. The online submission process follows a standard format and contributors will be asked to confirm that all authors have agreed to the submission and that the article is not currently being considered for publication by any other paper-based or electronic journal. All submissions should avoid the use of insensitive or demeaning language. In particular, authors should use ‘dementia-friendly’ language in positioning people living with dementia in their article and avoid using pejorative terms such as ‘demented’ or ‘suffering from dementia’. We recommend that authors refer to the Dementia Engagement and Empowerment Project (DEEP) guidance [http://dementiavoices.org.uk/resources/deep-guides/], which was developed by people living with dementia and offers a range of advice and support, including writing dementia-friendly information. Alternatively, Alzheimer’s Australia sets out guidelines for dementia-friendly language
[https://fightdementia.org.au/sites/default/files/NATIONAL/documents/lang.... Please also consider how you are using abbreviations in your submission. Whilst QoL (for quality of life) and MMSE (for Mini-mental State Examination) may have common usage, please try to avoid unnecessary abbreviations in the submission of your manuscript, such as PWD (for people with dementia) and abbreviations that detract from the overall flow of the manuscript.

Special editions of Dementia are commissioned by the journal’s Editors and we welcome suggestions for such copy. If you would like to consider being a Guest Editor(s) of Dementia and have a topic in mind, please contact prof John Keady (John.Keady@manchester.ac.uk) and/or prof Penny Harris (pharris@jcu.edu) in the first instance.

Reviews: Books and educational resources for review / requests to review should be sent to Dr Caroline Swarbrick, School of Nursing, Midwifery and Social Work, Jean McFarlane Building (6th floor), The University of Manchester, University Place, Oxford Road, Manchester. M13 9PL, UK (email: caroline.swarbrick@manchester.ac.uk)

Innovative Practice: The journal also welcomes short papers on various aspects of innovative practice in dementia care. Jo Moriarty at King’s College London, UK (jo.moriarty@kcl.ac.uk) is the Editor for this section of the journal which is published twice a year. Submissions for Innovative Practice are generally between 2500-3000 words, but longer papers can be received in exceptional circumstances. Please visit http://mc.manuscriptcentral.com/dementia to log in and submit your Innovative Practice article online. This section of the journal is not peer reviewed.

For all other original articles, including literature reviews, Dementia operates a strictly anonymous peer review process in which the reviewer’s name is withheld from the author and the author’s name from the reviewer(s). We aim for each manuscript to be reviewed by two reviewers but the Editors reserve the right to return the decision to the author with more, or less, reviews depending upon the context and circumstances of the submitted article. All manuscripts are reviewed as rapidly as possible and correspondence with the main author will be undertaken electronically. All submitting authors should be mindful that their manuscript may be reviewed by a person living with dementia as part of the journal’s Editorial Board.

This Journal is a member of the Committee on Publication Ethics.

Please read the guidelines below then visit the Journal’s submission site http://mc.manuscriptcentral.com/dementia to upload your manuscript. Please note that manuscripts not conforming to these guidelines may be returned.

Only manuscripts of sufficient quality that meet the aims and scope of Dementia will be reviewed.

There are no fees payable to submit or publish in this journal.

As part of the submission process you will be required to warrant that you are submitting your original work, that you have the rights in the work, that you are submitting the work for first publication in the Journal and that it is not being considered for publication elsewhere and has not already been published elsewhere, and that you have obtained and can supply all necessary permissions for the reproduction of any copyright works not owned by you.

1. What do we publish?

1.1 Aims & Scope

Before submitting your manuscript to Dementia, please ensure you have read the Aims & Scope.
1.2 Article Types

Dementia welcomes original research or original contributions to the existing literature on social research and dementia.

Brief articles should be up to 3000 words and more substantial articles between 5000 and 6000 words (references are not included in this word limit). At their discretion, the Editors will also consider articles of greater length.

Dementia also welcomes papers on various aspects of innovative practice in dementia care. Submissions for this part of the journal should be between 2,500-3,000 words. Innovative practice papers should include the words 'Innovative Practice' after the title of their article when submitting to the journal. For further information about innovative practice papers, please refer to the guidelines.

The journal also publishes book reviews.

1.3 Writing your paper

The SAGE Author Gateway has some general advice and on how to get published, plus links to further resources.

1.3.1 Make your article discoverable

When writing up your paper, think about how you can make it discoverable. The title, keywords and abstract are key to ensuring readers find your article through search engines such as Google. For information and guidance on how best to title your article, write your abstract and select your keywords, have a look at this page on the Gateway: How to Help Readers Find Your Article Online.

2. Editorial policies

2.1 Peer review policy

Dementia operates a strictly anonymous peer review process in which the reviewer’s name is withheld from the author and, the author’s name from the reviewer. Each manuscript is reviewed by at least two referees. All manuscripts are reviewed as rapidly as possible.

As part of the submission process you will be asked to provide the names of peers who could be called upon to review your manuscript. Recommended reviewers should be experts in their fields and should be able to provide an objective assessment of the manuscript. Please be aware of any conflicts of interest when recommending reviewers. Examples of conflicts of interest include (but are not limited to) the below:

The reviewer should have no prior knowledge of your submission,

The reviewer should not have recently collaborated with any of the authors,

Reviewer nominees from the same institution as any of the authors are not permitted.

Please note that the Editors are not obliged to invite any recommended/opposed reviewers to assess your manuscript.

2.2 Authorship

All parties who have made a substantive contribution to the article should be listed as authors. Principal authorship, authorship order, and other publication credits should be based on the relative
scientific or professional contributions of the individuals involved, regardless of their status. A student is usually listed as principal author on any multiple-authored publication that substantially derives from the student’s dissertation or thesis.

2.3 Acknowledgements

All contributors who do not meet the criteria for authorship should be listed in an Acknowledgements section. Examples of those who might be acknowledged include a person who provided purely technical help, or a department chair who provided only general support.

Any acknowledgements should appear first at the end of your article prior to your Declaration of Conflicting Interests (if applicable), any notes and your References.

2.4 Funding

Dementia requires all authors to acknowledge their funding in a consistent fashion under a separate heading. Please visit the Funding Acknowledgements page on the SAGE Journal Author Gateway to confirm the format of the acknowledgment text in the event of funding, or state that: This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

2.5 Declaration of conflicting interests

It is the policy of Dementia to require a declaration of conflicting interests from all authors enabling a statement to be carried within the paginated pages of all published articles.

Please ensure that a ‘Declaration of Conflicting Interests’ statement is included at the end of your manuscript, after any acknowledgements and prior to the references. If no conflict exists, please state that ‘The Author(s) declare(s) that there is no conflict of interest’. For guidance on conflict of interest statements, please see the ICMJE recommendations here.

2.6 Research ethics and patient consent

Medical research involving human subjects must be conducted according to the World Medical Association Declaration of Helsinki.

Submitted manuscripts should conform to the ICMJE Recommendations for the Conduct, Reporting, Editing, and Publication of Scholarly Work in Medical Journals, and all papers reporting animal and/or human studies must state in the methods section that the relevant Ethics Committee or Institutional Review Board provided (or waived) approval. Please ensure that you have provided the full name and institution of the review committee, in addition to the approval number.

For research articles, authors are also required to state in the methods section whether participants provided informed consent and whether the consent was written or verbal.

Information on informed consent to report individual cases or case series should be included in the manuscript text. A statement is required regarding whether written informed consent for patient information and images to be published was provided by the patient(s) or a legally authorized representative.

Please also refer to the ICMJE Recommendations for the Protection of Research Participants.

3. Publishing Policies

3.1 Publication ethics
SAGE is committed to upholding the integrity of the academic record. We encourage authors to refer to the Committee on Publication Ethics’ International Standards for Authors and view the Publication Ethics page on the SAGE Author Gateway.

3.1.1 Plagiarism

Dementia and SAGE take issues of copyright infringement, plagiarism or other breaches of best practice in publication very seriously. We seek to protect the rights of our authors and we always investigate claims of plagiarism or misuse of published articles. Equally, we seek to protect the reputation of the journal against malpractice. Submitted articles may be checked with duplication-checking software. Where an article, for example, is found to have plagiarised other work or included third-party copyright material without permission or with insufficient acknowledgement, or where the authorship of the article is contested, we reserve the right to take action including, but not limited to: publishing an erratum or corrigendum (correction); retracting the article; taking up the matter with the head of department or dean of the author's institution and/or relevant academic bodies or societies; or taking appropriate legal action.

3.1.2 Prior publication

If material has been previously published it is not generally acceptable for publication in a SAGE journal. However, there are certain circumstances where previously published material can be considered for publication. Please refer to the guidance on the SAGE Author Gateway or if in doubt, contact the Editor at the address given below.

3.2 Contributor's publishing agreement

Before publication, SAGE requires the author as the rights holder to sign a Journal Contributor’s Publishing Agreement. SAGE’s Journal Contributor’s Publishing Agreement is an exclusive licence agreement which means that the author retains copyright in the work but grants SAGE the sole and exclusive right and licence to publish for the full legal term of copyright. Exceptions may exist where an assignment of copyright is required or preferred by a proprietor other than SAGE. In this case copyright in the work will be assigned from the author to the society. For more information please visit the SAGE Author Gateway.

3.3 Open access and author archiving

Dementia offers optional open access publishing via the SAGE Choice programme. For more information please visit the SAGE Choice website. For information on funding body compliance, and depositing your article in repositories, please visit SAGE Publishing Policies on our Journal Author Gateway.

4. Preparing your manuscript for submission

4.1 Formatting

The preferred format for your manuscript is Word. LaTeX files are also accepted. Word and (La)TeX templates are available on the Manuscript Submission Guidelines page of our Author Gateway.

Language and terminology. Jargon or unnecessary technical language should be avoided, as should the use of abbreviations (such as coded names for conditions). Please avoid the use of nouns as verbs (e.g. to access), and the use of adjectives as nouns (e.g. dents). Language that might be deemed sexist or racist should not be used.
Abbreviations. As far as possible, please avoid the use of initials, except for terms in common use. Please provide a list, in alphabetical order, of abbreviations used, and spell them out (with the abbreviations in brackets) the first time they are mentioned in the text.

4.2 Artwork, figures and other graphics

For guidance on the preparation of illustrations, pictures and graphs in electronic format, please visit SAGE’s Manuscript Submission Guidelines.

Figures supplied in colour will appear in colour online regardless of whether or not these illustrations are reproduced in colour in the printed version. For specifically requested colour reproduction in print, you will receive information regarding the costs from SAGE after receipt of your accepted article.

4.3 Supplementary material

This journal is able to host additional materials online (e.g. datasets, podcasts, videos, images etc) alongside the full-text of the article. For more information please refer to our guidelines on submitting supplementary files.

4.4 Reference style

Dementia adheres to the APA reference style. View the APA guidelines to ensure your manuscript conforms to this reference style.

4.5 English language editing services

Authors seeking assistance with English language editing, translation, or figure and manuscript formatting to fit the journal’s specifications should consider using SAGE Language Services. Visit SAGE Language Services on our Journal Author Gateway for further information.

5. Submitting your manuscript

Dementia is hosted on SAGE Track, a web based online submission and peer review system powered by ScholarOne™ Manuscripts. Visit http://mc.manuscriptcentral.com/dementia to login and submit your article online.

IMPORTANT: Please check whether you already have an account in the system before trying to create a new one. If you have reviewed or authored for the journal in the past year it is likely that you will have had an account created. For further guidance on submitting your manuscript online please visit ScholarOne Online Help.

Innovative Practice papers must be submitted via the online system. If you would like to discuss your paper prior to submission, please email Jo Moriarty jo.moriarty@kcl.ac.uk.

Books for review should be sent to: Book Review Editor, Dementia, Caroline Swarbrick University of Manchester, UK caroline.swarbrick@manchester.ac.uk

5.1 ORCID

As part of our commitment to ensuring an ethical, transparent and fair peer review process SAGE is a supporting member of ORCID, the Open Researcher and Contributor ID. ORCID provides a persistent digital identifier that distinguishes researchers from every other researcher and, through integration in key research workflows such as manuscript and grant submission, supports automated linkages between researchers and their professional activities ensuring that their work is recognised.
We encourage all authors to add their ORCIDs to their SAGE Track accounts and include their ORCIDs as part of the submission process. If you don’t already have one you can create one here.

5.2 Information required for completing your submission

You will be asked to provide contact details and academic affiliations for all co-authors via the submission system and identify who is to be the corresponding author. These details must match what appears on your manuscript. At this stage please ensure you have included all the required statements and declarations and uploaded any additional supplementary files (including reporting guidelines where relevant).

5.3 Permissions

Please also ensure that you have obtained any necessary permission from copyright holders for reproducing any illustrations, tables, figures or lengthy quotations previously published elsewhere. For further information including guidance on fair dealing for criticism and review, please see the Copyright and Permissions page on the SAGE Author Gateway.

6. On acceptance and publication

6.1 SAGE Production

Your SAGE Production Editor will keep you informed as to your article’s progress throughout the production process. Proofs will be sent by PDF to the corresponding author and should be returned promptly. Authors are reminded to check their proofs carefully to confirm that all author information, including names, affiliations, sequence and contact details are correct, and that Funding and Conflict of Interest statements, if any, are accurate. Please note that if there are any changes to the author list at this stage all authors will be required to complete and sign a form authorising the change.

6.2 Online First publication

Online First allows final articles (completed and approved articles awaiting assignment to a future issue) to be published online prior to their inclusion in a journal issue, which significantly reduces the lead time between submission and publication. Visit the SAGE Journals help page for more details, including how to cite Online First articles.

6.3 Access to your published article

SAGE provides authors with online access to their final article.

6.4 Promoting your article

Publication is not the end of the process! You can help disseminate your paper and ensure it is as widely read and cited as possible. The SAGE Author Gateway has numerous resources to help you promote your work. Visit the Promote Your Article page on the Gateway for tips and advice. In addition, SAGE is partnered with Kudos, a free service that allows authors to explain, enrich, share, and measure the impact of their article. Find out how to maximise your article’s impact with Kudos.

7. Further information

Any correspondence, queries or additional requests for information on the manuscript submission process should be sent to the Dementia editorial office as follows: dem.pra@sagepub.com
